PREFACE

The Handbook of Chemistry and Physics, continuing the policy of the past, is being revised at frequent intervals.

The general features and scheme of arrangement, which have received extensive endorsement in former editions have been retained. The aim throughout has been to present in condensed form as large an amount of accurate, reliable and up-to-date information in the fields of chemistry and physics as was consistent with convenience in form and the possibility of wide utility and distribution. A very large proportion of the tables have been compiled especially for the Handbook from various authoritative collections of data and from the current journals.

Since the beginning special consideration has been given to the requests and suggestions of those who have used former editions. In this way it has been hoped to develop the book along lines most acceptable to those interested in a volume of this type. Suggestions and contributions are received each year from many eminent chemists and physicists including members of the teaching profession and those engaged in industrial work. We believe this coöperation to have been of very great value in the growth and development of the work.

An attempt has been made to include material on all branches of chemistry and physics and the closely allied sciences, which would be likely to find any extended use. On the other hand, in order to retain the convenience of moderate dimensions and at the same time allow for natural growth due to the extension of knowledge in these sciences, and logical additions along lines already developed, it has seemed necessary to exclude types of material of use only in certain highly specialized lines of work.

Chemistry and physics, always closely related sciences, have been brought into much more intimate relations by the more recent developments of research. To an increasing extent the student of either science should have a knowledge of the other. It would seem that there should be a large field for a single volume containing the constants and formulæ of the two sciences together with mathematical and conversion tables adequate for accurate computation. The generous response which the previous editions have met indicates that the volumes have been found useful and it is with the hope of even more completely meeting the needs of the chemists and physicists of the English speaking world that succeeding editions are offered.

CHARLES D. HODGMAN

PREFACE TO THE FORTIETH EDITION

The question of the information to be included in any book which is revised annually is a difficult one. All editors attempt to strike a balance between information useful to the areas that the book is most likely to serve. This policy serves the purpose of keeping the book up-to-date and in providing students and research personnel with data and information in one book rather than in widely separated books, reference works, industrial libraries, and government publications.

In continuing the practice of collecting information of use to physicists and chemists there have been added to our book for the Fortieth Edition the following tables:

Electron Physics Tables
Physical Constants of the Rare Earth Compounds
Physical Constants of Inorganic Hydrides
Thermal Conductivity of Oven-dry Wood Across the Grain
Thermal Conductivity of Wood Across the Grain at Various Moisture Content Values
Thermodynamic Properties of the Elements
Thermodynamic Properties of the Oxides
Langevin Functions
Superconducting Transition Temperatures, Magnetic Threshold Fields at Absolute Zero, Electronic Constants and DeBye Temperatures for Superconducting Elements
Chelating Agents
Ion Exchange Resins.

There has, in addition, been a revision of certain areas of the book. In particular the following information and tables have been revised:

The section of Definitions and Formulas
Physical Constants of Ozone and Oxygen
Viscosity of Aqueous Glycerol Solutions
Trade Names of Commercial Resins and Plastics
Properties of Plastics
Inclusion of new element No. 102—Nobelium—in the section Description of the Elements, in the Atomic Weights, and the Table of Isotopes.

Obviously it is not possible to add an unlimited amount of information each year. Nevertheless, the editors continue to welcome suggestions for new material to be placed in the Handbook of Chemistry and Physics. Such suggestions are not only helpful but are necessary if the book is to continue to serve the specialists who are working in significant fields but who are outside of the generalized knowledge of most scientists.

As in the past the editors are grateful to those who have assisted us with the present revision.

Cleveland, Ohio,
July 15, 1958.

ANTIDOTES OF POISONS

Acetic Acid.—Emetics, magnesia, chalk, soap, oil.

Acetylene.—Same as for carbon monoxide.

Arsenic, Rat Poison, Paris Green.—Milk, raw egg, sweet oil, lime water, flour and water.

Carbolic Acid.—Any soluble non-toxic sulphate, after provoking vomiting with zinc sulphate; uncooked white of egg in abundance, milk of lime, saccharate of calcium, olive or castor oil with magnesia in suspension, ice, washing the stomach with equal parts water and vinegar; give alcohol or whiskey or about four fluid ounces camphorated oil at one dose.

Carbon Monoxide.—Remove to fresh air immediately and call for pulmotor; apply artificial respiration for at least one hour or until the pulmotor arrives. Administration of oxygen containing 5% of carbon dioxide is beneficial; inhalation of ammonia or amyl nitrite is often of value.

Chloroform, Chloral, Ether.—Dash cold water on head and chest, artificial respiration.

Ethylene.—Same as for carbon monoxide.

Gas (illuminating).—Same as for carbon monoxide.

Hydrochloric Acid.—Magnesia, alkali carbonates, albumen, ice.

Hydrocyanic or Prussic Acid.—Hydrogen peroxide internally, and artificial respiration, breathing ammonia or chlorine from chlorinated lime, ferrous sulphate followed by potassium carbonate, emetics, warmth.

Iodine.—Emetics, stomach siphon, starchy foods in abundance, sodium thiosulphate.

Lead Acetate.—Emetics, stomach siphon, sodium, potassium or magnesium sulphates, milk, albumen.

Mercuric Chloride or Corrosive Sublimate.—Zinc sulphate, emetics, stomach siphon, white of egg, milk, chalk, castor oil, table salt, reduced iron.

Nitrate of Silver.—Salt and water.

Nitric Acid.—Same as for hydrochloric acid.

Opium, Morphine, Laudanum, Paregoric, etc.—Strong coffee, hot bath. Keep awake and moving at any cost.

Phosphoric Acid.—Same as for hydrochloric.

ANTIDOTES OF POISONS (Continued)

Sodium Hydroxide or Potassium Hydroxide.—Vinegar, lemon juice, orange juice, oil, milk.

Sulfuric Acid.—Same as for hydrochloric acid with the addition of soap or oil.

Sulfurous Acid or Sulfur Dioxide.—Mustard plaster on chest; narcotics, expectorants.

Wood Alcohol (Methyl Alcohol or Methanol).—Emetic or wash out stomach (stomach tube) with a solution of 10 grains sodium citrate per ounce of water. Give milk, white of egg or flour in water; purgative of magnesium sulfate (15 grams); stimulate and combat collapse. In case of cardiac or pulmonary failure use artificial respiration. Physicians may administer atropine, digitalin or strychnine as stimulants; to cause perspiration and elimination of the poison use 0.1 grain of pilocarpine hydrochloride.

BURNS AND SCALDS

Exclude air by thin paste of starch, flour, or baking soda. Ordinary oils such as Vaseline petroleum jelly, olive or castor oil, lard or cream may also be used except for phosphorus burns. Lime water mixed with an equal part of raw linseed oil makes an excellent dressing. An especially valuable material for all burns is picric acid gauze which may be applied in the form of a compress.

After treatment with any of the above materials, cover with a cloth or with cotton and hold in place with a light bandage.

Apply a freshly prepared 5% tannic acid solution. Place several layers of sterile gauze over the burned area, saturate with the tannic acid solution and bandage loosely.

CHEMICAL BURNS

With either, wash off as quickly as possible with a large quantity of water. Water from a tap may be allowed to flow over burns.

Acids

While the injury is being washed, have procured lime water or lime water and raw linseed oil mixed together in equal proportions or a mixture of baking soda and water or soap suds and apply freely. For acid in the eye wash as quickly as possible with water and then with lime water.

Alkalis

Wash with a large quantity of water as for acid burns. Neutralize with weak vinegar, hard cider or lemon juice. For lime or other strong alkali burns in the eye wash with weak solution of vinegar or with olive oil or a saturated solution of boric acid.

Bromine.—Sponge immediately with a strong solution of sodium thiosulfate until all the bromine color is gone, then wash off the mildly poisonous sodium thiosulfate with plenty of water.

FIRE PRECAUTIONS AND CHEMICAL HAZARDS

Acetone.—Dilute with a spray of water to avoid spread of burning liquid. Use suitable gas mask.

Alcohol.—See under acetone.

Ammonia.—Use water and dilute acid. Use suitable gas mask.

Benzol or Benzene.—Use water to cool containers which are endangered; extinguish flame with sand, earth, fire-foam or carbon tetrachloride fire extinguishers. Use suitable gas mask.

Calcium Carbide.—Do not use water as this generates acetylene, an inflammable and explosive gas; cut off electric current to avoid ignition of gas. Remove containers to a dry place. Use gas mask.

Carbon Disulfide.—Use water to cool containers which are endangered; extinguish blaze with sand, earth, fire-foam or carbon tetrachloride fire extinguishers. Use suitable gas mask.

Carbon Tetrachloride.—When a carbon tetrachloride type extinguisher is used on a fire in a confined space, the fire should be attacked from outside the enclosure, if possible, or the area should be vacated immediately after the fire is out. No one should return to the enclosure until the air is cleared of smoke and fumes. These precautions should be observed regardless of the means by which the fire is extinguished, however, since fire in a confined space rapidly produces a toxic atmosphere.

Do not put carbon tetrachloride on a sodium fire, violent explosions may be caused.

Celluloid.—Use large volumes of water and sand. The smoke contains oxides of nitrogen which are injurious. Use suitable gas mask.

Chlorine.—Spray with water. The pungent nature of the gas makes the use of a gas mask imperative.

Collodion.—See under carbon disulfide.

Ether.—See under carbon disulfide.

Gasoline.—See under carbon disulfide.

Hydrochloric Acid.—Use large volumes of water also chalk or soda. Use gas mask.

Hydrocyanic or Prussic Acid.—Suitable gas mask is essential because of the extremely poisonous nature of the vapors. Provide ventilation.

Lacquer Solvents.—See under carbon disulfide.

Magnesium.—Do not use water. Use sand or earth to extinguish flames. Remove containers to a dry place.

Nitric Acid and Oxides of Nitrogen.—Use large volumes of water. Do not use sand or earth. Use gas mask.

Potassium.—Do not use water. Remove containers to a dry place. Extinguish flames with sand or earth. For storage, potassium is kept immersed in petroleum.

Potassium Hydroxide.—Use large volumes of water or dilute acids.

Phosphorus.—Use water and wet sand. Use gas mask. For storage, white phosphorus must be kept immersed in water. Red phosphorus is less dangerous.

Sodium.—See under potassium.

Sodium Hydroxide.—See under potassium hydroxide.

Sulfur.—Extinguish with water or sand. Use gas mask.

Sulfuric Acid.—See under hydrochloric acid.

Turpentine.—See under acetone.

USE OF MATHEMATICAL TABLES

For a complete discussion of the principles and use of mathematical tables, textbooks on the subject should be consulted. The following brief statements are intended to give only sufficient information to make possible the intelligent use of the tables, omitting for the most part any attempt at treating the theory and principles.

Exponential Method of Expressing Numbers—For convenience in writing and manipulation, numbers are often expressed as factors of appropriate powers of 10. The following examples will illustrate:

2,380,000,000. may be written 2.38×10^9
238. may be written 2.38×10^2
.238 may be written 2.38×10^{-1}
.000000238 may be written 2.38×10^{-7}

Logarithms—The logarithm of a number is the exponent of that power to which another number, the base, must be raised to give the number first named. Any positive number greater than 1 might serve as a base. Two have been selected, yielding two systems of logarithms. One base, 2.718 . . . . usually indicated by the letter e, gives rise to a system of logarithms convenient in higher mathematics. These are called natural, Napierian, or hyperbolic logarithms. Reference will be made to their use in a subsequent paragraph.

The other base used is 10, giving logarithms particularly adapted to use in computation, called common or Briggian logarithms. Tables of logarithms given without designation are invariably of this latter type.

Since most numbers are incommensurable powers of ten, a common logarithm, in general, consists of an integer which is called the characteristic and an endless decimal, the mantissa.

It is to be observed that the common logarithms of all numbers expressed by the same figures in the same order with the decimal point in different positions have different characteristics but the same mantissa. To illustrate:—if the decimal point stand after the first figure of a number, counting from the left, the characteristic is 0; if after two figures, it is 1; if after three figures, it is 2, and so forth. If the decimal point stand before the first significant figure the characteristic is -1, usually written $\bar{1}$; if there is one zero between the decimal point and the first significant figure it is 2 and so on. For example: $\log 256 = 2.40824$, $\log 2.56 = 0.40824$, $\log 0.256 = \bar{1}.40824$, $\log 0.00256 = \bar{3}.40824$. The two latter are often written $\log 0.256 = 9.40824 - 10$, $\log 0.00256 = 7.40824 - 10$.

A method of determining characteristics of logarithms is to write the number with one figure to the left of the decimal point multiplied by the appropriate power of 10. The characteristic is then the exponent used. For example:

$$256{,}000{,}000 = 2.56 \times 10^8 \quad \log = 8.40824$$
$$0.000000256 = 2.56 \times 10^{-7} \quad \log = \overline{7}.40824 \text{ or } 3.40824-10$$

Inasmuch as the characteristic may be determined by inspection the mantissas only are given in tables of common logarithms.

To find the logarithm of a number:

For a number of four figures, take out the tabular mantissa on a line with the first three figures of the number and under its fourth figure. The characteristic is determined as previously explained.

For a number of less than four figures, supply zeros to make a four figure number and take the value of the mantissa from the tables as before. For example: $\log 2 = \log 2.000 = 0.30103$.

For a number of more than four figures, take the tabular value of the mantissa for the first four figures; find the difference between this mantissa and the next greater tabular mantissa and multiply the difference so found by the remaining figures of the number as a decimal and add the product to the mantissa of the first four figures. For example: to find log 46.762.

$$\log 46.76 = 1.66987$$

Tabular difference between this mantissa and that for 4677 is .00010.

$$\begin{aligned} \therefore \log 46.762 &= 1.66987 + .2 \times .00010 \\ &= 1.66987 + .00002 \\ &= 1.66989 \end{aligned}$$

To find the number corresponding to a given logarithm:

If the mantissa is found exactly in the table, join the figure at the top which is directly above the given mantissa to the three figures on the line at the left and place the decimal point according to the characteristic of the logarithm. For example, $\log^{-1}$ (antilogarithm) $3.39967 = 2510$.

If the mantissa is not found exactly in the table it is necessary to interpolate. For example, $\log^{-1} 3.40028 = 2513. + {}^{9}/_{18} = 2513.5$.

The column of proportional parts at the right of each page of the table shows, under the heading of the various tabular differences, the parts of these differences which correspond to the digits from 1 to 9 in the fifth place. This makes it possible to take out a logarithm for a five figure number or to find an antilogarithm of the same number of significant figures with increased facility, usually by inspection.

USE OF MATHEMATICAL TABLES (Continued)

The following formulae express the relations on which the use of logarithms is based:

$$\begin{aligned} \log ab &= \log a + \log b \\ \log \frac{a}{b} &= \log a - \log b \\ \log a^n &= n \times \log a \\ \log \sqrt[n]{a} &= \frac{\log a}{n}. \end{aligned}$$

The following examples will serve as illustrations:

1. $52600 \times 0.00381 \times 2.74 = 549.1$

$$\begin{aligned} \log 52600 &= 4.72099 \\ \log 0.00381 &= \bar{3}.58092 \\ \log 2.74 &= 0.43775 \\ \hline \text{Sum:} \quad &= 2.73966 \\ \text{Antilogarithm} &= 549.1 \end{aligned}$$

The sum is the logarithm of the product, the mantissa of which is 73966. On looking up this mantissa in the logarithm tables we see that it corresponds to the digits 5491. The characteristic is 2, hence there are three figures before the decimal point. The number corresponding to the logarithm, called the antilogarithm, is 549.1.

2. $0.00123 \div 52.7 = 0.00002334$

$$\begin{aligned} \log 0.00123 &= \bar{3}.08991 \\ \log \quad 52.7 &= 1.72181 \\ \hline \text{Subtracting} \quad & \bar{5}.36810 \\ \text{Antilog} \quad & 0.00002334 \end{aligned}$$

An Alternative method:

$$\begin{aligned} \log 0.00123 &= 7.08991 - 10 \\ \log \quad 52.7 &= 1.72181 \\ \hline & 5.36810 - 10 \end{aligned}$$

The characteristic $\bar{5}$ (5. -10) shows four zeros after the decimal point before the first significant figure.

3. $\dfrac{273 \times 780}{292 \times 760} \times 15 \times 0.09 = 1.295$

$$\begin{aligned} \log \ 273 &= 2.43616 \\ \log \ 780 &= 2.89209 \\ \log \ \ 15 &= 1.17609 \\ \log 0.09 &= \bar{2}.95424 \\ \hline \log \text{sum} &= 5.45858 \end{aligned}$$

$$\begin{aligned} \log 292 &= 2.46538 \\ \log 760 &= 2.88081 \\ \hline \log \text{denominator} &= 5.34619 \end{aligned}$$

$$\begin{aligned} \log \text{numerator} &= 5.45858 \\ \log \text{denominator} &= 5.34619 \\ \hline \text{subtracting} &= 0.11239 \\ \text{antilogarithm} &= 1.295 \end{aligned}$$

USE OF MATHEMATICAL TABLES (Continued)

As division may be accomplished by multiplying by the reciprocal of a number, the above may be considerably simplified. The logarithm of the reciprocal of a number, called the cologarithm, is readily obtained from the table by subtracting the logarithm of the number from zero. This may readily be read off from the table of mantissas. Change the sign of the characteristic algebraically adding to it −1, then mentally subtract each figure of the mantissa from 9 proceeding from left to right, the last figure being subtracted from 10. The example then is:

$$\begin{array}{lcl}
\log\ 273 & = & 2.43616 \\
\log\ 780 & = & 2.89209 \\
\log\ 15 & = & 1.17609 \\
\log\ 0.09 & = & \bar{2}.95424 \\
\text{colog}\ 292 & = & \bar{3}.53462 \\
\text{colog}\ 760 & = & \bar{3}.11919 \\
\hline
 & & 0.11239
\end{array}$$

4. $(0.00098)^4 = 9.224 \times 10^{-13}$

$$\begin{array}{lcl}
\log 0.00098 & = & \bar{4}.99123 \\
 & & 4 \\
\hline
 & & 3.96492\text{(a)} \\
\bar{4} \times 4 & & \overline{16}.\quad\text{(b)} \\
\hline
\log (0.00098)^4 & = & \overline{13}.96492\text{(c)} \\
\text{antilog} = 9.224 \times 10^{-13} & &
\end{array}$$

An alternative method:

$$\begin{array}{lcr}
\log 0.00098 & = & 6.99123-10 \\
 & & 4 \\
\hline
 & & 27.96492-40 \\
 & & \text{or } 7.96492-20 \\
 & & \text{or } \overline{13}.96492 \\
\text{antilog} & = & 9.224 \times 10^{-13}
\end{array}$$

In the above it will be noted that the mantissa is always positive hence the multiplication of the mantissa shown at (a) while (b) shows the multiplication of the characteristic. (c) is the algebraic sum.

5. $\sqrt[5]{492} = 3.455$
$\log 492 = 2.69197$

Dividing the logarithm by 5 gives as the logarithm of the root 0.53839 the antilogarithm of which is 3.455 both characteristic and mantissa being positive. When the characteristic is negative and not evenly divisible by the root to be taken a modification of the logarithm is necessary.

6. $\sqrt[3]{0.000372} =$

$$\begin{array}{lcll}
\log 3.72 \times 10^{-4} & = & \bar{4}.57054 & \text{(a)} \\
 & = & 26.57054-30 & \text{(b)}
\end{array}$$

dividing (b) by 3 gives 8.85685−10 which may be written

$\bar{2}.85685$ and is the logarithm of the root sought, the antilogarithm of which is 0.07192.

7. $0.000372^{1.2} = 0.000076674$

log 0.000372 $= \bar{4}.57054$

or $6.57054 - 10$

1.2

$7.88465 - 12$

antilogarithm 0.000076674

8. $(0.000372)^{-1.32} = 33642$

colog 0.000372 $= 3.42946$

1.32

4.52689

antilogarithm 33642

Four-Place Logarithms—This short table on two facing pages makes possible logarithmic computation precise to four significant figures, (three without interpolation). The mantissa is given complete and the proportional parts indicated for each line.

Four-Place Antilogarithms—Some computers prefer to use separate tables for determining antilogarithms; the table being entered from the margins with the logarithm and the number being found in the body of the table. Such a table is given to accompany the four-place logarithms.

Five-Place Logarithms—For computation involving five significant figures, (four without interpolation) the five-place table will be adequate. Since the first two figures will be the same for several lines of the table they are given in the first line only. The point at which these first two figures change is indicated by an asterisk. While space does not permit the proportional parts for each line, tables will be found for each tabular difference.

The supplementary table following the five-place logarithms, giving seven-place logarithms for numbers of five significant figures from 10,000 to 12,000 will be found convenient to increase precision and avoid the inconvenience of interpolation where the differences are large.

Logarithms of the Trigonometric Functions—Logarithms of the functions are given for each minute from 0-360°.

The quantity − 10 is to be appended to all logarithms of the sine and cosine, to logarithms of the tangent from 0-45° and of the cotangent from 45-90°.

With degrees indicated at either side of the top of the page use the column headings at the top. With degrees stated at the bottom of the page use the column designations at the bottom.

With degrees at the left (top or bottom) use the minute column at the left, and with degrees on the right side of the page use the minute column at the right.

USE OF MATHEMATICAL TABLES (Continued)

To illustrate the proper employment of headings for angles in the four quadrants—

$\log\sin 6^\circ 24' = 9.04715-10$ $\log\sin 186^\circ 24' = 9.04715-10$
$\log\sin 83^\circ 15' = 9.99698-10$ $\log\sin 263^\circ 15' = 9.99698-10$
$\log\cos 96^\circ 41' = 9.06589-10$ $\log\cos 276^\circ 41' = 9.06589-10$
$\log\cos 173^\circ 49' = 9.99747-10$ $\log\cos 353^\circ 49' = 9.99747-10$

For the accurate determination of values where the tabular differences are large, the values of CS and CT are given. The following equations indicate their use.

To find the logarithm of the functions of an angle:

For angles 0–3°
$\log\sin\theta = \log\theta'' - CS$
$\log\tan\theta = \log\theta'' - CT$
$\log\cot\theta = \operatorname{colog}\tan\theta$

For angles 87–90°
$\log\cos\theta = \log(90^\circ-\theta)'' - CS$
$\log\cot\theta = \log(90^\circ-\theta)'' - CT$
$\log\tan\theta = \operatorname{colog}\cot\theta$

To find the angle:

For angles 0–3°
$\log\theta'' = \log\sin\theta + CS$
$\log\theta'' = \log\tan\theta + CT$

For angles 87–90°
$\log(90^\circ-\theta)'' = \log\cos\theta + CS$
$\log(90^\circ-\theta)'' = \log\cot\theta + CT$

In the above expressions, θ'' and $(90^\circ-\theta)''$ are used to indicate the value of the angles expressed in seconds. The values in the body of the table are the cologarithms and should be used as indicated above.

The values of the logarithms S and T are also given in a separate table. For these the following relations hold:

To find the functions of an angle.

$\log\sin\theta = \log\theta'' + S$ $\log\cos\theta = \log(90^\circ-\theta)'' + S$
$\log\tan\theta = \log\theta'' + T$ $\log\cot\theta = \log(90^\circ-\theta)'' + T$

To find the angle.

$\log\theta'' = \log\sin\theta - S$ $\log(90^\circ-\theta)'' = \log\cos\theta - S$
$\log\theta'' = \log\tan\theta - T$ $\log(90^\circ-\theta)'' = \log\cot\theta - T$

Where the values of CS and CT are given, the angles expressed in seconds are given in the supplementary column at the left.

The tabular differences are given under the headings "d" and "c.d.", the latter referring to the common difference for the tangent and cotangent. Tables of proportional parts ("P.P.") facilitate interpolation. At the bottom of each column will be found special proportional parts between the tabular differences for the tangent or cotangent and those for the sine or cosine. These are useful when one function is to be obtained directly from the other without determining the angle.

For example, suppose log tan θ is given as 9.67644 and log cos θ is required. The difference between the given logarithm and that given in the table, 9.67622 (opposite 25° 23′), is 22.

USE OF MATHEMATICAL TABLES (Continued)

The tabular differences of the two logarithmic functions at this place are 32 and 6. In the proportional table for $\frac{6}{32}$, 22 corresponds to 4; this, subtracted from the tabular logarithmic cosine 9.95591, gives the required log cos $\theta = 9.95587$.

The symbols $\bar{5}$ and $\dot{5}$ are used to indicate how the terminal 5 has been derived. For example, the logarithm 8.83075 is more fully given as 8.8307495 while the value $9.4082\dot{5}$ is derived from 9.4082539. Thus, in rounding off to four places, a number ending in $\bar{5}$ should be decreased but a number ending in $\dot{5}$ should be increased.

Natural Trigonometric Functions—Values of the natural trigonometric functions of angles are given for each minute from 0–360°.

For degrees indicated at the top of the page use the column headings at the top. For degrees indicated at the bottom use the column indications at the bottom.

With degrees at the left of each block (top or bottom), use the minute column at the left and with degrees at the right of each block use the minute column at the right.

Natural Functions and their Logarithms are given for angles in degrees and tenths from 0 to 90 degrees.

Natural Functions and their Logarithms are given for angles in radians and hundredths, from 0 to 2 radians.

Haversines—Values of $(1 - \cos\theta)/2$ for angles between 0 and 180° are given to four significant figures. The four-place mantissas of the logarithms of the haversines are also given. The correct characteristic must be provided in each case.

The listed values of the haversines were derived from values which were computed to seven significant figures. The logarithms were independently derived from the more exact values of the haversines and are, therefore, in many cases not the exact value of the logarithm of the haversine as listed. This is notably true at the beginning of the table where the logarithm can be given with more exactness than the function.

Natural Logarithms—The natural logarithms of numbers from 0.000 to 999. are given in a group of four tables. The method of finding logarithms of numbers not included in the tables is indicated at the beginning of the third page. A convenient table of constants occurs at the top of the fourth page.

The first page gives the natural logarithms of numbers from 0.000 to 0.499. Since the characteristics change rapidly for the smaller numbers, they are indicated *above* the mantissa in the first line. In the second and following lines the characteristics are given at the left only. For example, $\log_e 0.004 = -5.52146$; $\log_e 0.014 = -4.26870$.

The succeeding pages give the natural logarithms of numbers up to 999.

USE OF MATHEMATICAL TABLES (Continued)

Exponential Functions—Values of e^x, log e^x and e^{-x} where e is the base of the natural system of logarithms 2.71828 . . . and x has values from 0 to 10. Facilitating the solution of exponential equations, these tables also serve as a table of natural or Naperian antilogarithms. For instance if the logarithm or exponent $x = 3.26$ the corresponding number or value of e^x is 26.050. Its reciprocal e^{-x} is .038388.

Hyperbolic Functions—The table gives the values and logarithms of the hyperbolic sine x, cosine x, tangent x and cotangent x for values of x from 0 to 10.

Degrees-Radians—This table gives the value in radians to five significant figures; for each 10 minutes from $0° \, 0'$ to $90° \, 0'$; for each degree from 90 to 180; for each 10 degrees from 180 to 480. Values are also given for each minute from 0–60′ and for each second from 0–60″.

Tables are also provided to facilitate changing from degrees and decimal fractions to radians, from decimal fractions of a degree to minutes and seconds and the reverse operations.

Numerical Tables—The first section gives the reciprocals of numbers from 0 to 1000 and circumferences and areas of circles with diameters having these values. Reciprocals and circumferences for values not listed can be obtained by an appropriate shift of the decimal point.

The second section is devoted to squares, cubes and roots. The squares and cubes from 1 to 1000 are given exactly. The roots are given to seven significant figures. Since the square roots of $10n$ are given, values of the square roots from 1 to 10,000 may be found directly. For the square roots of numbers below and above this range, use may be made of the following relations: $\sqrt{100n} = 10\sqrt{n}$; $\sqrt{1000n} = 10\sqrt{10n}$; $\sqrt{\tfrac{1}{10}n} = \tfrac{1}{10}\sqrt{10n}$; $\sqrt{\tfrac{1}{100}n} = \tfrac{1}{10}\sqrt{n}$; $\sqrt{\tfrac{1}{1000}n} = \tfrac{1}{100}\sqrt{10n}$. For example, the square root of 0.268 may be found by using the form, $\sqrt{0.268} = \tfrac{1}{100}\sqrt{10 \times 268}$. The tabular value for the square root of $10n$ for 268 is 51.76872. Hence, the desired root is 0.5176872.

Values of cube roots for all numbers from 1 to 100,000 will be found directly in the table. Cube roots for numbers above or below this range will be found from the following relations: $\sqrt[3]{1000n} = 10\sqrt[3]{n}$; $\sqrt[3]{10{,}000n} = 10\sqrt[3]{10n}$; $\sqrt[3]{100{,}000n} = 10\sqrt[3]{100n}$; $\sqrt[3]{\tfrac{1}{10}n} = \tfrac{1}{10}\sqrt[3]{100n}$; $\sqrt[3]{\tfrac{1}{100}n} = \tfrac{1}{10}\sqrt[3]{10n}$; $\sqrt[3]{\tfrac{1}{1000}n} = \tfrac{1}{10}\sqrt[3]{n}$. For example, the cube root of 731,000 may be found by using the form, $\sqrt[3]{731{,}000} = 10\sqrt[3]{731}$. The tabular value of the root for 731 is 9.008223. The desired root is, therefore, 90.08223.

Powers of Numbers—This table is given to supplement the values of squares and cubes of numbers found in the preceding numerical table. The larger numbers are expressed exponentially to at least seven significant figures. The approximate value written as a whole number may be obtained by shifting the decimal point to the right by the number of places indicated in the exponent of 10 shown at the head of each group of values. For example: the approximate value of 33^8 is found in the table as 14.064086×10^{11}. Written as a whole number it is 1,406,408,600,000.

Factorials and their Logarithms—The product $n \times (n-1) \times (n-2) \times \cdots \times 1$ is called factorial n, expressed as $n!$ or $\underline{|n}$. For example: factorial $5 = 5 \times 4 \times 3 \times 2 \times 1 = 120$. Factorials are very often met with in series. For purposes of computation in such cases the table giving the values of the factorials and of their logarithms for numbers from 1 to 100 is provided. The values of the factorials are expressed exponentially to 5 significant figures.

A brief table of exact values and reciprocals of factorials is to be found on page 165.

Factors for Computing Probable Errors—The probable error of a series of n measures $a_1, a_2, a_3 \ldots a_n$, the mean of which is m, is given by the expression,

$$e = \frac{0.6745}{\sqrt{n-1}}\sqrt{(m-a_1)^2 + (m-a_2)^2 + \cdots (m-a_n)^2}$$

The probable error of the mean is,

$$E = \frac{0.6745}{\sqrt{n(n-1)}}\sqrt{(m-a_1)^2 + (m-a_2)^2 + \cdots (m-a_n)^2}$$

The following approximate equations are convenient forms for computation,

$$e = 0.8453\frac{\Sigma d}{\sqrt{n(n-1)}}$$

$$E = 0.8453\frac{\Sigma d}{n\sqrt{n-1}}$$

The symbol Σd represents the arithmetical sum of the deviations.

For convenience in computing the probable error the value of several of the factors involved is given for values of n from 2 to 100.

USE OF MATHEMATICAL TABLES (Continued)

Probability of Occurrence of Deviations—The significance of deviations is indicated by this table. The probability of occurrence of deviations as great as or greater than any specific value is given for various ratios of deviation to probable error and also with respect to the standard deviation σ. The probability of occurrence is stated in per cent or chances in 100. The odds against occurrence are also stated. The probable error is $0.6745 \times (\sigma)$.

Normal Curve of Error—If, for a large number of observations, the frequency y, of the occurrence of an error of magnitude t be plotted, a curve results whose equation may be written,

$$y = \frac{1}{\sqrt{2\pi}} e^{-t^2/2}$$

The area, ordinates and derivatives for this curve given in the table are useful in the treatment of observational data. A text on statistical methods should be consulted for a complete explanation.

Factors and Primes—The table presents the prime factors of *all* factorable numbers and the logarithms of all prime numbers from 1 to 2000.

MISCELLANEOUS CONSTANTS

Mean radius of the earth, 3959 miles = 6371 kilometers.

1 degree of latitude at 40° = 69 miles.

International nautical mile = 1.151 statute miles = 1,852 meters = 6,076.10333 feet.

Mean density of the earth, 5.522 grams per cm^3.

Constant of gravitation, $K = 6.670 \times 10^{-8}$ = the attraction in dynes between two gram masses one centimeter apart.

Acceleration due to gravity at sea level, lat. 45° = 980.665 cm. per sec. per sec. = 32.172 feet per sec. per sec.

Length of seconds pendulum at sea level, lat. 45° = 99.358 cm. = 39.117 in.

1 knot = 101.3 ft/min = 1.689 ft/sec = 1.152 mi/hr.

1 micron = 10^{-4} cm. 1 ångström unit = 10^{-8} cm.

Mass of hydrogen atom = $1.67339_3 \pm 0.00031 \times 10^{-24}$ gram.

Avogadro's number = $6.0247 \pm .0002 \times 10^{23}$ $mole^{-1}$ (Physical scale).

Planck's constant = $6.6254 \pm .0002 \times 10^{-27}$ erg sec.

Density of mercury at 0° C. = 13.59509 g. per cm^3.

Density of water, maximum at 3.98° C. = 0.999973 g. per cm^3.

Density of dry air at 0° C. and 760 mm. = .001293 g. per cm^3.

Velocity of sound in dry air at 0° C., 33,136 cm. per sec. = 1087.1 feet per sec.

Velocity of light in a vacuum = 2.99776×10^{10} cm. per sec. = 9.83514×10^{8} feet per sec. = 186,272 mi./sec. (Birge, 1941).

Heat equivalent of fusion of water 79.63 cal. (15° C.) per gram.

Heat equivalent of vaporization of water, 539.55 cal. (15° C.) per gram.

Coefficient of expansion of gases, .003665.

Specific heat of air, at constant pressure, 0.238.

Electrochemical equivalent of silver, 0.001118 g. per sec. per int. ampere.

Mean wave length of sodium light, .00005893 cm. or 5893 ångström units.

Absolute wave length of red cadmium line in air, 760 mm. pressure, 15° C.; 6438.4696 ångström units.

GREEK ALPHABET

---

* This table gives the logarithms of the decimal fractions which are negative numbers. For example $\log 0.61 = -0.2147 = 9.7853 - 10$. It should be noted that the entries as given can be used conveniently to find cologarithms of positive numbers. Every positive number $N = P \cdot (10)^k$, where $0 < P \leqq 1$. Since $\text{colog } N = -\log N$, it follows that $\text{colog } N = -\log P - k$.

For example $\text{colog } 0.61 = -\log 0.61 = 0.2147$; $\text{colog } 61 = 0.2147 - 2$; and $\text{colog } 0.00061 = 3.2147$.

LOGARITHMS OF THE TRIGONOMETRIC FUNCTIONS

Logarithms of the functions are given for each minute from 0-360°.

The quantity −10 is to be appended to all logarithms of the sine and cosine, to logarithms of the tangent from 0-45° and of the cotangent from 45-90°.

With degrees indicated at either side of the top of the page use the column headings at the top. With degrees stated at the bottom of the page use the column designations at the bottom.

With degrees at the left (top or bottom) use the minute column at the left, and with degrees on the right side of the page use the minute column at the right.

The method of determining the functions of small angles by the auxiliary quantities S and T is given in the section explaining the use of the mathematical tables at the front of the volume.

LOGARITHMS OF TRIGONOMETRIC FUNCTIONS

Min.	Values of S, − 10 to be appended					Values of T, − 10 to be appended					Sec.

P. P.

NATURAL TRIGONOMETRIC FUNCTIONS

Values of the trigonometric functions of angles for each minute from 0–360°.

For degrees indicated at the top of the page use the column headings at the top. For degrees indicated at the bottom use the column indications at the bottom.

With degrees at the left of each block (top or bottom), use the minute column at the left and with degrees at the right of each block use the minute column at the right.

If natural trigonometric function tables are used for angle measures greater than 90° and less than 360°, appropriate signs for the functions must be supplied in accordance with the quadrant in which the angle measure belongs.

NATURAL FUNCTIONS

* Values of the cosine, tangent and cotangent for angles in the table, 1.58 radians and above, are negative. As a consequence the logarithms of the functions involved are for their absolute values. For example log |cos 1.90| = 9.50959 − 10.

HAVERSINES

$\text{hav}\ \theta = \frac{1}{2}\ \text{vers}\ \theta = \frac{1}{2}(1 - \cos\theta) = \sin^2 \frac{1}{2}\theta$
$\text{hav}\ (-\theta) = \text{hav}\ \theta$
$\text{hav}\ (180^\circ - \theta) = \text{hav}\ (180^\circ + \theta) = 1 - \text{hav}\ \theta$
Characteristics of the logarithms are omitted.

NATURAL OR NAPERIAN LOGARITHMS (Continued)

To find the natural logarithm of a number which is $\frac{1}{10}$, $\frac{1}{100}$, $\frac{1}{1000}$, etc. of a number whose logarithm is given, subtract from the given logarithm $\log_e 10$, $2 \log_e 10$, $3 \log_e 10$, etc.

To find the natural logarithm of a number which is 10, 100, 1000, etc. times a number whose logarithm is given, add to the given logarithm $\log_e 10$, $2 \log_e 10$, $3 \log_e 10$, etc.

$\log_e 10 = 2.30258\ 50930$
$2 \log_e 10 = 4.60517\ 01860$
$3 \log_e 10 = 6.90775\ 52790$
$4 \log_e 10 = 9.21034\ 03720$
$5 \log_e 10 = 11.51292\ 54650$
$6 \log_e 10 = 13.81551\ 05580$
$7 \log_e 10 = 16.11809\ 56510$
$8 \log_e 10 = 18.42068\ 07440$
$9 \log_e 10 = 20.72326\ 58369$
$10 \log_e 10 = 23.02585\ 09299$

See preceding table for logarithms for numbers between 0.000 and 0.999.

MILS—RADIANS—DEGREES

1 mil = 0.00098175 radians = 0.05625° = 3.375′ = 202.5″
1000 mils = 0.98175 radians = 56.25°
6400 mils = 360° = 2π radians
1 radian = 1018.6 mils
1° = 17.777778 mils
1′ = 0.296296 mils
1″ = 0.0049382 mils

DEGREES—RADIANS

1 radian = 57° 17′ 44″.80625

	log
1 radian = 57.29577 95131 degrees	1.75812 26324
1 radian = 3437.74677 07849 minutes	3.53627 38828
1 radian = 206264.80625 seconds	5.31442 51332
1 degree = 0.01745 32925 19943 radians	8.24187 73676–10
1 minute = 0.00029 08882 08666 radians	6.46372 61172–10
1 second = 0.00000 48481 36811 radians	4.68557 48668–10

DEGREES—RADIANS

The table gives in radians the angle which is expressed in degrees and minutes at the side and top. Angles expressed to the nearest minute and second can readily be converted to radians by adding to the equivalent of the whole number of degrees the equivalents of the minutes and seconds found on the third page of this table.

* If 3.214 is desired in degrees, minutes and seconds it is obtained as follows:

3 = 171° 53′ 14.4″
.2 = 11° 27′ 33.0″
.01 = 0° 34′ 22.6″
.004 = 0° 13′ 45.1″
3.214 = 184° 8′ 55.1″

DEGREES AND DECIMAL FRACTIONS TO RADIANS

The table below facilitates conversion of an angle expressed in degrees and decimal fractions into radians. To convert 25.78 into radians, find the equivalents, successively, of 20°, 5°, 0°.7, 0°.08 and add.

Deg.	Radians	Deg.	Radians	Deg.	Radians	Deg.	Radians	Deg.	Radians
10	0.174533	1	0.017453	0.1	0.001745	0.01	0.000175	0.001	0.000017

Reciprocals, Circumference and Area of Circles

As a matter of convenience, the values of 1000 × $(1/n)$ are given in the table. To obtain the actual value of the reciprocal, shift the decimal point three places to the left.

Circumferences and areas of circles are given for the values of n as the diameter.

n	$1000\frac{1}{n}$	Circumference πn	Area $\frac{\pi n^2}{4}$	n	$1000\frac{1}{n}$	Circumference πn	Area $\frac{\pi n^2}{4}$

Squares, Cubes and Roots

Roots of numbers other than those given directly may be found by the following relations:

$\sqrt{100n} = 10\sqrt{n}$; $\sqrt{1000n} = 10\sqrt{10n}$; $\sqrt{\frac{1}{10}n} = \frac{1}{10}\sqrt{10n}$; $\sqrt{\frac{1}{100}n} = \frac{1}{10}\sqrt{n}$. $\sqrt{\frac{1}{1000}n} = \frac{1}{100}\sqrt{10n}$; $\sqrt[3]{1000n} = 10\sqrt[3]{n}$; $\sqrt[3]{10{,}000n} = 10\sqrt[3]{10n}$; $\sqrt[3]{100{,}000n} = 10\sqrt[3]{100n}$; $\sqrt[3]{\frac{1}{10}n} = \frac{1}{10}\sqrt[3]{100n}$; $\sqrt[3]{\frac{1}{100}n} = \frac{1}{10}\sqrt[3]{10n}$; $\sqrt[3]{\frac{1}{1000}n} = \frac{1}{10}\sqrt[3]{n}$.

PROBABILITY OF OCCURRENCE OF DEVIATIONS

Valid for thirty or more samples.

Probability of occurrence, expressed as per cent, and odds against a deviation as great or greater than that designated is given for various ratios of the deviation to the probable error and to the standard deviation.

(From Pearl, Medical Biometry and Statistics, W. B. Saunders Company, publishers, by permission.)

Ratio dev. to P.E.	Probable occurrence %	Odds against, to 1	Ratio dev. to std. dev.	Probable occurrence %	Odds against, to 1

NORMAL CURVE OF ERROR

$$\textbf{Normal Curve}\quad \phi(x) = \frac{1}{\sqrt{2\pi}}\, e^{-\frac{x^2}{2}}$$

The following table gives values of the area under the curve from the ordinate at $t = 0$ to the ordinate for the values of t given in the column at the left. Values of the ordinate and of the second, third and fourth derivatives are also given.

t	Area	Ordinate $\phi(x)$	Second derivative $\phi''(x)$	Third derivative $\phi'''(x)$	Fourth derivative $\phi^{iv}(x)$	t	Area	Ordinate $\phi(x)$	Second derivative $\phi''(x)$	Third derivative $\phi'''(x)$	Fourth derivative $\phi^{iv}(x)$

STATISTICAL TABLES

"t" Test of Significance Between Two Sample Means ($\bar{x}_1$ and $\bar{x}_2$).

(Use Fisher's t distribution)

Paired variates:

$$t = \frac{\bar{d}}{\sqrt{\frac{\Sigma(d_i - \bar{d})^2}{N(N-1)}}} \text{ with } N - 1 \text{ degrees of freedom}$$

where $\bar{d} = \bar{x}_1 - \bar{x}_2$
$d_1 = x_{11} - x_{21}$
$d_2 = x_{12} - x_{22}$ etc.
N = sample size

Unpaired variates:

$$t = \frac{\bar{x}_1 - \bar{x}_2}{\sqrt{\frac{\Sigma_i(x_i - \bar{x}_1)^2 + \Sigma_i(x_{2i} - \bar{x}_2)^2}{N_1 + N_2 - 2}\left(\frac{1}{N_1} + \frac{1}{N_2}\right)}}$$

with $N_1 + N_2 - 2$ degrees of freedom

where N_1 = size of sample 1
N_2 = size of sample 2

Chi Square Table

The column headings "P" are probabilities, while the body of the table gives values of χ^2; the left column the degrees of freedom. The probability of a value $\chi^2 \geqq$ than the value specified is thus obtained. For $n = 20$, $P(\chi^2 \geqq 10.851)$ the table gives .95, and accordingly by subtraction $P(\chi^2 \leqq 10.851)$ is .05.

F Test for Equality of Variances

$$F = \frac{\sigma_1^2}{\sigma_2^2}$$

where σ_1^2 = variance of sample with size N_1
σ_2^2 = variance of sample with size N_2
with $N_1 - 1$ = degrees of freedom for numerator
$N_2 - 1$ = degrees of freedom for denominator

(Use Snedecor's F distribution)

For degrees of freedom greater than 30, the expression $\sqrt{2\chi^2} - \sqrt{2n' - 1}$ may be used as a normal deviate with unit variance, where n' is the number of degrees of freedom.

FACTORS AND PRIMES

If n is prime the mantissa of its logarithm is given.

n	0	1	2	3	4
0	....	**0000000**	**3010300**	**4771213**	2^2
1	$2 \cdot 5$	**0413927**	$2^2 \cdot 3$	**1139434**	$2 \cdot 7$
2	$2^2 \cdot 5$	$3 \cdot 7$	$2 \cdot 11$	**3617278**	$2^3 \cdot 3$
3	$2 \cdot 3 \cdot 5$	**4913617**	2^5	$3 \cdot 11$	$2 \cdot 17$
4	$2^3 \cdot 5$	**6127839**	$2 \cdot 3 \cdot 7$	**6334685**	$2^2 \cdot 11$
5	$2 \cdot 5^2$	$3 \cdot 17$	$2^2 \cdot 13$	**7242759**	$2 \cdot 3^3$
6	$2^2 \cdot 3 \cdot 5$	**7853298**	$2 \cdot 31$	$3^2 \cdot 7$	2^6
7	$2 \cdot 5 \cdot 7$	**8512583**	$2^3 \cdot 3^2$	**8633229**	$2 \cdot 37$
8	$2^4 \cdot 5$	3^4	$2 \cdot 41$	**9190781**	$2^2 \cdot 3 \cdot 7$

$d\,\mathrm{sech}^{-1}\,u = -u^{-1}(1 - u^2)^{-\frac{1}{2}}\,du$
$d\,\mathrm{csch}^{-1}\,u = -u^{-1}(u^2 + 1)^{-\frac{1}{2}}du$

TABLE OF INTEGRALS

The following points should be observed when using this table.

1. A constant of integration is to be supplied with the answers for indefinite integrals.

2. Logarithmic expressions are to base $e = 2.71828 \cdots$, unless otherwise specified, and are to be evaluated for the absolute value of the arguments involved therein.

3. All angles are measured in radians, and inverse trigonometric functions represent principal angles.

4. If the application of a formula produces either a zero denominator or a radical involving the unit $i = \sqrt{-1}$ in the result, there is always available another form of the answer which avoids this difficulty. In many of the results, the excluded values are specified, but when such are omitted it is presumed that one can tell what these should be, especially when difficulties of the type herein mentioned are obtained.

ELEMENTARY FORMS

1. $\int a\,dx = ax.$

2. $\int a \cdot f(x)dx = a\int f(x)dx.$

3. $\int \phi(y)dx = \int \frac{\phi(y)}{y'}\,dy,$ where $y' = dy/dx.$

4. $\int (u + v)\,dx = \int u\,dx + \int v\,dx,$ where u and v are any functions of x.

5. $\int u\,dv = u\int dv - \int v\,du = uv - \int v\,du.$

6. $\int u\frac{dv}{dx}\,dx = uv - \int v\frac{du}{dx}\,dx.$

7. $\int x^n\,dx = \frac{x^{n+1}}{n+1},$ except $n = -1.$

8. $\int \frac{f'(x)\,dx}{f(x)} = \log f(x),$ $[d\,f(x) = f'(x)\,dx].$

9. $\int \frac{dx}{x} = \log x,$ or $\log(-x).$

10. $\int \frac{f'(x)\,dx}{2\sqrt{f(x)}} = \sqrt{f(x)},$ $[d\,f(x) = f'(x)\,dx].$

11. $\int e^x\,dx = e^x.$

12. $\int e^{ax}\,dx = e^{ax}/a.$

13. $$\int b^{ax}\,dx = \frac{b^{ax}}{a \log b}.$$

14. $$\int \log x\,dx = x \log x - x.$$

15. $$\int a^{x} \log a\,dx = a^{x}.$$

16. $$\int \frac{dx}{a^2 + x^2} = \frac{1}{a} \tan^{-1}\left(\frac{x}{a}\right), \text{ or } -\frac{1}{a} \cot^{-1}\left(\frac{x}{a}\right).$$

17. $$\int \frac{dx}{a^2 - x^2} = \frac{1}{a} \tanh^{-1}\left(\frac{x}{a}\right), \text{ or } \frac{1}{2a} \log \frac{a + x}{a - x}.$$

18. $$\int \frac{dx}{x^2 - a^2} = -\frac{1}{a} \coth^{-1}\left(\frac{x}{a}\right), \text{ or } \frac{1}{2a} \log \frac{x - a}{x + a}.$$

19. $$\int \frac{dx}{\sqrt{a^2 - x^2}} = \sin^{-1}\left(\frac{x}{a}\right), \text{ or } -\cos^{-1}\left(\frac{x}{a}\right).$$

20. $$\int \frac{dx}{\sqrt{x^2 \pm a^2}} = \log\left(x + \sqrt{x^2 \pm a^2}\right).$$

21. $$\int \frac{dx}{x\sqrt{x^2 - a^2}} = \frac{1}{a} \cos^{-1}\left(\frac{a}{x}\right).$$

22. $$\int \frac{dx}{x\sqrt{a^2 \pm x^2}} = -\frac{1}{a} \log\left(\frac{a + \sqrt{a^2 \pm x^2}}{x}\right).$$

23. $$\int \frac{dx}{x\sqrt{a + bx}} = \frac{2}{\sqrt{-a}} \tan^{-1}\sqrt{\frac{a + bx}{-a}}, \text{ or}$$
$$\frac{-2}{\sqrt{a}} \tanh^{-1}\sqrt{\frac{a + bx}{a}}, \text{ or } \frac{1}{\sqrt{a}} \log \frac{\sqrt{a + bx} - \sqrt{a}}{\sqrt{a + bx} + \sqrt{a}}.$$

Forms Containing $(a + bx)$

24. $$\int (a + bx)^n dx = \frac{(a + bx)^{n+1}}{(n + 1)b}, \text{ except } n = -1.$$

25. $$\int x\,(a + bx)^n dx = \frac{1}{b^2(n + 2)}(a + bx)^{n+2}$$
$$-\frac{a}{b^2(n + 1)}(a + bx)^{n+1}, \text{ except } n = -1 \text{ or } -2.$$

26. $$\int x^2\,(a + bx)^n\,dx = \frac{1}{b^3}\left[\frac{(a + bx)^{n+3}}{n + 3} - 2a\,\frac{(a + bx)^{n+2}}{n + 2} + a^2\,\frac{(a + bx)^{n+1}}{n + 1}\right].$$

27. $\displaystyle \int x^m (a+bx)^n\,dx = \frac{x^{m+1}(a+bx)^n}{m+n+1} + \frac{an}{m+n+1} \int x^m (a+bx)^{n-1}\,dx.$

28. $\displaystyle \int x^m (a+bx)^n\,dx = \frac{1}{a(n+1)}\left[-x^{m+1}(a+bx)^{n+1} + (m+n+2)\int x^m(a+bx)^{n+1}\,dx\right].$

29. $\displaystyle \int \frac{dx}{a+bx} = \frac{1}{b}\log(a+bx).$

30. $\displaystyle \int \frac{dx}{(a+bx)^2} = -\frac{1}{b(a+bx)}.$

31. $\displaystyle \int \frac{dx}{(a+bx)^3} = -\frac{1}{2b(a+bx)^2}.$

32. $\displaystyle \int \frac{xdx}{a+bx} = \frac{1}{b^2}[a+bx-a\log(a+bx)].$

33. $\displaystyle \int \frac{xdx}{(a+bx)^2} = \frac{1}{b^2}\left[\log(a+bx)+\frac{a}{a+bx}\right].$

34. $\displaystyle \int \frac{xdx}{(a+bx)^3} = \frac{1}{b^2}\left[-\frac{1}{a+bx}+\frac{a}{2(a+bx)^2}\right].$

35. $\displaystyle \int \frac{xdx}{(a+bx)^n} = \frac{1}{b^2}\left[\frac{-1}{(n-2)(a+bx)^{n-2}} + \frac{a}{(n-1)(a+bx)^{n-1}}\right], n \neq 1, 2.$

36. $\displaystyle \int \frac{x^2dx}{a+bx} = \frac{1}{b^3}\left[\frac{1}{2}(a+bx)^2 - 2a(a+bx) + a^2\log(a+bx)\right].$

37. $\displaystyle \int \frac{x^2\,dx}{(a+bx)^2} = \frac{1}{b^3}\left[a+bx-2a\log(a+bx)-\frac{a^2}{a+bx}\right].$

38. $\displaystyle \int \frac{x^2\,dx}{(a+bx)^3} = \frac{1}{b^3}\left[\log(a+bx)+\frac{2a}{a+bx}-\frac{a^2}{2(a+bx)^2}\right].$

39. $\displaystyle \int \frac{x^2\,dx}{(a+bx)^n} = \frac{1}{b^3}\left[\frac{-1}{(n-3)(a+bx)^{n-3}} + \frac{2a}{(n-2)(a+bx)^{n-2}} - \frac{a^2}{(n-1)(a+bx)^{n-1}}\right], n \neq 1, 2, 3.$

40. $\displaystyle \int \frac{dx}{x(a+bx)} = -\frac{1}{a}\log\frac{a+bx}{x}.$

41. $\displaystyle \int \frac{dx}{x(a+bx)^2} = \frac{1}{a(a+bx)} - \frac{1}{a^2}\log\frac{a+bx}{x}.$

42. $$\int \frac{dx}{x^2(a+bx)} = -\frac{1}{ax} + \frac{b}{a^2}\log\frac{a+bx}{x}.$$

43. $$\int \frac{dx}{x^2(a+bx)^2} = -\frac{a+2\,bx}{a^2x\,(a+bx)} + \frac{2b}{a^3}\log\frac{a+bx}{x}.$$

FORMS CONTAINING $c^2 \pm x^2$, $x^2 - c^2$

44. $$\int \frac{dx}{c^2+x^2} = \frac{1}{c}\tan^{-1}\frac{x}{c}, \text{ or } \frac{1}{c}\sin^{-1}\frac{x}{\sqrt{c^2+x^2}}.$$

45. $$\int \frac{dx}{c^2-x^2} = \frac{1}{2c}\log\frac{c+x}{c-x}, \text{ or } \frac{1}{c}\tanh^{-1}\left(\frac{x}{c}\right).$$

46. $$\int \frac{dx}{x^2-c^2} = \frac{1}{2c}\log\frac{x-c}{x+c}, \text{ or } -\frac{1}{c}\coth^{-1}\left(\frac{x}{c}\right).$$

FORMS CONTAINING $a + bx$ AND $a' + b'x$

47. $$\int \frac{dx}{(a+bx)(a'+b'x)} = \frac{1}{ab'-a'b}\cdot\log\left(\frac{a'+b'x}{a+bx}\right).$$

48. $$\int \frac{x\,dx}{(a+bx)(a'+b'x)} = \frac{1}{ab'-a'b}\left[\frac{a}{b}\log(a+bx) - \frac{a'}{b'}\log(a'+b'x)\right].$$

49. $$\int \frac{dx}{(a+bx)^2(a'+b'x)} = \frac{1}{ab'-a'b}\left(\frac{1}{a+bx} + \frac{b'}{ab'-a'b}\log\frac{a'+b'x}{a+bx}\right).$$

50. $$\int \frac{x\,dx}{(a+bx)^2(a'+b'x)} = \frac{-a}{b(ab'-a'b)(a+bx)} - \frac{a'}{(ab'-a'b)^2}\log\frac{a'+b'x}{a+bx}.$$

51. $$\int \frac{x^2\,dx}{(a+bx)^2(a'+b'x)} = \frac{a^2}{b^2(ab'-a'b)(a+bx)} + \frac{1}{(ab'-a'b)^2}\left[\frac{a'^2}{b'}\log(a'+b'x) + \frac{a(ab'-2\,a'b)}{b^2}\log(a+bx)\right].$$

52. $$\int \frac{dx}{(a+bx)^n(a'+b'x)^m} = \frac{1}{(m-1)(ab'-a'b)}\left(\frac{-1}{(a+bx)^{n-1}(a'+b'x)^{m-1}} - (m+n-2)b\int\frac{dx}{(a+bx)^n(a'+b'x)^{m-1}}\right).$$

53. $$\int \frac{a+bx}{a'+b'x}\,dx = \frac{bx}{b'} + \frac{ab'-a'b}{b'^2}\log(a'+b'x).$$

$$54.\ \int \frac{(a+bx)^m dx}{(a'+b'x)^n} = -\frac{1}{(n-1)(ab'-a'b)}\left[\frac{(a+bx)^{m+1}}{(a'+b'x)^{n-1}} + b(n-m-2)\int \frac{(a+bx)^m\,dx}{(a'+b'x)^{n-1}}\right]$$

$$= -\frac{1}{b'(n-m-1)}\left[\frac{(a+bx)^m}{(a'+b'x)^{n-1}} + m(ab'-a'b)\int \frac{(a+bx)^{m-1}dx}{(a'+b'x)^n}\right]$$

LAPLACE TRANSFORMS

The following tables of Operations and Transforms were taken from "Modern Operational Mathematics in Engineering" by permission from the author, R. V. Churchill, and the publisher, McGraw-Hill Book Company, Inc.

The operational method for solving differential equations makes use of the Laplace transformation which associates a given function $F(t)$ with a second function $f(s)$, so that

$$f(s) = L\{F(t)\} = \int_0^\infty e^{-st}F(t)\,dt,$$

where t = a real variable, $F(t)$ = a real function of t; $F(t) = 0$, $t < 0$; $f(s)$ = a function of s; s = a complex variable; and $e = 2.71828\ldots$

$f(s)$ is called the Laplace transform of $F(t)$

$F(t)$ can also be expressed as follows:

$$F(t) = \frac{1}{2\pi i}\int_{a-i\infty}^{a+i\infty} e^{st}f(s)\,ds$$

where a is chosen to the right of any singularity of $f(s)$.

The following tables give many useful theorems and important transform pairs.

LAPLACE OPERATIONS

	$F(t)$	$f(s)$
1	$F(t)$	$\int_0^\infty e^{-st}F(t)\,dt$
2	$AF(t) + BG(t)$	$Af(s) + Bg(s)$
3	$F'(t)$	$sf(s) - F(+0)$
4	$F^{(n)}(t)$	$s^n f(s) - s^{n-1}F(+0) - s^{n-2}F'(+0) - \cdots - F^{(n-1)}(+0)$
5	$\int_0^t F(\tau)\,d\tau$	$\frac{1}{s} f(s)$
6	$\int_0^t \int_0^\tau F(\lambda)\,d\lambda\,d\tau$	$\frac{1}{s^2} f(s)$
7	$\int_0^t F_1(t-\tau)F_2(\tau)\,d\tau = F_1 * F_2$	$f_1(s)f_2(s)$
8	$tF(t)$	$-f'(s)$
9	$t^n F(t)$	$(-1)^n f^{(n)}(s)$
10	$\frac{1}{t} F(t)$	$\int_s^\infty f(x)\,dx$
11	$e^{at}F(t)$	$f(s-a)$
12	$F(t-b)$, where $F(t) = 0$ when $t < 0$	$e^{-bs}f(s)$
13	$\frac{1}{c} F\left(\frac{t}{c}\right)$	$f(cs)$
14	$\frac{1}{c} e^{\frac{bt}{c}} F\left(\frac{t}{c}\right)$	$f(cs-b)$
15	$F(t+a) = F(t)$	$\dfrac{\int_0^a e^{-st}F(t)\,dt}{1-e^{-as}}$
16	$F(t+a) = -F(t)$	$\dfrac{\int_0^a e^{-st}F(t)\,dt}{1+e^{-as}}$
17	$F_1(t)$, the half-wave rectification of $F(t)$ in No. 16	$\dfrac{f(s)}{1-e^{-as}}$
18	$F_2(t)$, the full-wave rectification of $F(t)$ in No. 16	$f(s) \coth \frac{as}{2}$
19	$\sum_1^m \frac{p(a_n)}{q'(a_n)} e^{a_n t}$	$\frac{p(s)}{q(s)}$, $q(s) = (s-a_1)(s-a_2)\cdots(s-a_m)$
20	$e^{at} \sum_{n=1}^{r} \frac{\phi^{(r-n)}(a)}{(r-n)!} \frac{t^{n-1}}{(n-1)!} + \cdots$	$\frac{p(s)}{q(s)} = \frac{\phi(s)}{(s-a)^r}$

LAPLACE TRANSFORMS

---

* Several additional transforms, especially those involving other Bessel functions, can be found in the tables by G. A. Campbell and R. M. Foster, "Fourier Integrals for Practical Applications," or N. W. McLachlan and P. Humbert, "Formulaire pour le calcul symbolique." In the tables by Campbell and Foster, only those entries containing the condition $0 < g$ or $k < g$, where g is our t, are Laplace transforms.

ALGEBRA

Factors and Expansions

$$(a \pm b)^2 = a^2 \pm 2ab + b^2.$$

$$(a \pm b)^3 = a^3 \pm 3a^2b + 3ab^2 \pm b^3.$$

$$(a \pm b)^4 = a^4 \pm 4a^3b + 6a^2b^2 \pm 4ab^3 + b^4.$$

$$a^2 - b^2 = (a - b)(a + b).$$

$$a^2 + b^2 = \left(a + b\sqrt{-1}\right)\left(a - b\sqrt{-1}\right).$$

$$a^3 - b^3 = (a - b)(a^2 + ab + b^2).$$

$$a^3 + b^3 = (a + b)(a^2 - ab + b^2).$$

$$a^4 + b^4 = \left(a^2 + ab\sqrt{2} + b^2\right)\left(a^2 - ab\sqrt{2} + b^2\right).$$

$$a^n - b^n = (a - b)(a^{n-1} + a^{n-2}b + \ldots . + b^{n-1}).$$

$$a^n - b^n = (a + b)(a^{n-1} - a^{n-2}b + \ldots . - b^{n-1}),$$

for even values of n.

$$a^n + b^n = (a + b)\ (a^{n-1} - a^{n-2}b + \ldots . + b^{n-1}),$$

for odd values of n.

$$a^4 + a^2b^2 + b^4 = (a^2 + ab + b^2)(a^2 - ab + b^2).$$

$$(a + b + c)^2 = a^2 + b^2 + c^2 + 2ab + 2ac + 2bc.$$

$$(a + b + c)^3 = a^3 + b^3 + c^3 + 3a^2(b + c) + 3b^2(a + c) + 3c^2(a + b) + 6abc.$$

$$(a + b + c + d + \ldots)^2 = a^2 + b^2 + c^2 + d^2 + \ldots + 2a(b + c + d + \ldots) + 2b(c + d + \ldots) + 2c(d + \ldots) + \ldots$$

See also under Series

Powers and Roots

$$a^x \times a^y = a^{(x+y)}. \qquad a^0 = 1 \text{ [if } a \neq 0]. \qquad (ab)^x = a^xb^x.$$

$$\frac{a^x}{a^y} = a^{(x-y)}. \qquad a^{-x} = \frac{1}{a^x}. \qquad \left(\frac{a}{b}\right)^x = \frac{a^x}{b^x}.$$

$$(a^x)^y = a^{xy}. \qquad a^{\frac{1}{x}} = \sqrt[x]{a}. \qquad \sqrt[x]{ab} = \sqrt[x]{a}\,\sqrt[x]{b}.$$

$$\sqrt[x]{\sqrt[y]{a}} = \sqrt[xy]{a}. \qquad a^{\frac{x}{y}} = \sqrt[y]{a^x}. \qquad \sqrt[x]{\frac{a}{b}} = \frac{\sqrt[x]{a}}{\sqrt[x]{b}}.$$

Proportion

If $\dfrac{a}{b} = \dfrac{c}{d}$, then $\dfrac{a + b}{b} = \dfrac{c + d}{d}$,

$$\frac{a - b}{b} = \frac{c - d}{d}, \qquad \frac{a - b}{a + b} = \frac{c - d}{c + d}.$$

ALGEBRA—(Continued)

SUMS OF NUMBERS

The sum of the first n numbers,—

$$\Sigma(n) = 1+2+3+4+5 \dots +n = \frac{n(n+1)}{2}$$

The sum of the squares of the first n numbers,

$$\Sigma(n^2) = 1^2+2^2+3^2+4^2+5^2 \dots +n^2 = \frac{n(n+1)(2n+1)}{6}$$

The sum of the cubes of the first n numbers,

$$\Sigma(n^3) = 1^3+2^3+3^3+4^3+5^3 \dots +n^3 = \frac{n^2(n+1)^2}{4}$$

ARITHMETICAL PROGRESSION

If a is the first term; l, the last term; d, the common difference; n, the number of terms and s, the sum of n terms,—

$$l = a + (n-1)d \qquad s = \frac{n}{2}(a+l)$$

$$s = \frac{n}{2}\left\{ 2a + (n-1)d \right\}$$

GEOMETRICAL PROGRESSION

If a is the first term; l, the last term; r, the common ratio; n, the number of terms and s, the sum of n terms,—

$$l = ar^{n-1} \qquad s = a\frac{(1-r^n)}{1-r}$$

$$s = a\frac{(r^n-1)}{r-1} \qquad s = \frac{lr-a}{r-1}$$

If n is infinity and r^2 less than unity,—

$$s = \frac{a}{1-r}$$

FACTORIALS

$\underline{\lfloor n} = n! = e^{-n}n^n\sqrt{2\pi n}$, approximately.

PERMUTATIONS

If M denote the number of permutations of n things taken p at a time,—

$$M = n(n-1)(n-2) \dots (n-p+1)$$

COMBINATIONS

If M denote the number of combinations of n things taken p at a time,—

$$M = \frac{n(n-1)(n-2) \dots (n-p+1)}{p!}$$

$$M = \frac{n!}{p!(n-p)!}$$

Quadratic Equations

Any quadratic equation may be reduced to the form, —

$$ax^2 + bx + c = 0$$

Then $$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}.$$

If a, b, and c, are real, then
if $b^2 - 4ac$ is positive, the roots are real and unequal;
if $b^2 - 4ac$ is zero, the roots are real and equal;
if $b^2 - 4ac$ is negative, the roots are imaginary and unequal;
a, b, and c, are rational.

Cubic Equations

A cubic equation, $y^3 + py^2 + qy + r = 0$ may be reduced to the form, —

$$x^3 + ax + b = 0$$

by substituting for y the value, $\left(x - \frac{p}{3}\right)$. Here

$$a = \tfrac{1}{3}(3q - p^2) \text{ and } b = \tfrac{1}{27}(2p^3 - 9pq + 27r).$$

For solution let, —

$$A = \sqrt[3]{-\frac{b}{2} + \sqrt{\frac{b^2}{4} + \frac{a^3}{27}}}, \qquad B = \sqrt[3]{-\frac{b}{2} - \sqrt{\frac{b^2}{4} + \frac{a^3}{27}}},$$

then the values of x will be given by,

$$x = A + B, \quad -\frac{A+B}{2} + \frac{A-B}{2}\sqrt{-3}, \quad -\frac{A+B}{2} - \frac{A-B}{2}\sqrt{-3}$$

If $\frac{b^2}{4} + \frac{a^3}{27} > 0$, there will be one real root and two conjugate imaginary roots.

If $\frac{b^2}{4} + \frac{a^3}{27} = 0$, there will be three real roots of which two at least are equal

If $\frac{b^2}{4} + \frac{a^3}{27} < 0$, there will be three real and unequal roots.

In the last case a trigonometric solution is useful. Compute the value of the angle ϕ in the expression, —

$$\cos\phi = -\frac{b}{2} \div \sqrt{\left(-\frac{a^3}{27}\right)},$$

then x will have the following values:—

$$2\sqrt{-\frac{a}{3}}\cos\frac{\phi}{3}, \qquad 2\sqrt{-\frac{a}{3}}\cos\left(\frac{\phi}{3} + 120°\right),$$

$$2\sqrt{-\frac{a}{3}}\cos\left(\frac{\phi}{3} + 240°\right).$$

APPROXIMATIONS

If a and b are small quantities, the following relations are approximately true,—

$$(1 \pm a)^m = 1 \pm ma,$$

$$(1 \pm a)^m (1 \pm b)^n = 1 \pm ma \pm nb.$$

If n is nearly equal to m,

$$\sqrt{mn} = \frac{n+m}{2}, \text{ approximately.}$$

If θ is a very small angle expressed in radians,—

$$\frac{\sin \theta}{\theta} = 1 \text{ and } \frac{\tan \theta}{\theta} = 1, \text{ approximately.}$$

SERIES

The expression in parentheses following certain of the series indicates the region of convergence. If not otherwise indicated it is to be understood that the series converges for all finite values of x.

BINOMIAL

$$(x+y)^n = x^n + nx^{n-1}y + \frac{n(n-1)}{2!}x^{n-2}y^2$$

$$+ \frac{n(n-1)(n-2)}{3!}x^{(n-3)}y^3 + \dots \quad (y^2 < x^2)$$

$$(1 \pm x)^n = 1 \pm nx + \frac{n(n-1)x^2}{2!} \pm \frac{n(n-1)(n-2)x^3}{3!} + \dots \text{ etc.} \quad (x^2 < 1)$$

$$(1 \pm x)^{-n} = 1 \mp nx + \frac{n(n+1)x^2}{2!} \mp \frac{n(n+1)(n+2)x^3}{3!} + \dots \text{ etc.} \quad (x^2 < 1)$$

$$(1 \pm x)^{-1} = 1 \mp x + x^2 \mp x^3 + x^4 \mp x^5 + \dots \quad (x^2 < 1)$$

$$(1 \pm x)^{-2} = 1 \mp 2x + 3x^2 \mp 4x^3 + 5x^4 \mp 6x^5 + \dots \quad (x^2 < 1)$$

TAYLOR'S SERIES

$$f(x+h) = f(x) + hf'(x) + \frac{h^2}{2!}f''(x) + \frac{h^3}{3!}f'''(x) + \dots$$

$$= f(h) + xf'(h) + \frac{x^2}{2!}f''(h) + \frac{x^3}{3!}f'''(h) + \dots$$

MACLAURIN'S SERIES

$$f(x) = f(o) + xf'(o) + \frac{x^2}{2!}f''(o) + \frac{x^3}{3!}f'''(o) + \dots$$

EXPONENTIAL

$$e = 1 + \frac{1}{1} + \frac{1}{2!} + \frac{1}{3!} + \frac{1}{4!} + \dots$$

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \frac{x^4}{4!} + \dots$$

$$a^x = 1 + x \log_e a + \frac{(x \log a)^2}{2!} + \frac{(x \log a)^3}{3!} + \dots$$

SERIES (Continued)

LOGARITHMIC

$$\log_e x = \frac{x-1}{x} + \frac{1}{2}\left(\frac{x-1}{x}\right)^2 + \frac{1}{3}\left(\frac{x-1}{x}\right)^3 + \dots \qquad (x > \tfrac{1}{2})$$

$$\log_e x = (x-1) - \tfrac{1}{2}(x-1)^2 + \tfrac{1}{3}(x-1)^3 - \dots \qquad (2 > x > 0)$$

$$\log_e x = 2\left[\frac{x-1}{x+1} + \frac{1}{3}\left(\frac{x-1}{x+1}\right)^3 + \frac{1}{5}\left(\frac{x-1}{x+1}\right)^5 + \dots\right] \qquad (x > 0)$$

$$\log_e(1+x) = x - \tfrac{1}{2}x^2 + \tfrac{1}{3}x^3 - \tfrac{1}{4}x^4 + \dots \qquad (-1 < x < 1)$$

$$\log_e(n+1) - \log_e(n-1) = 2\left[\frac{1}{n} + \frac{1}{3n^3} + \frac{1}{5n^5} + \dots\right]$$

$$\log_e(a+x) = \log_e a + 2\left[\frac{x}{2a+x} + \frac{1}{3}\left(\frac{x}{2a+x}\right)^3 + \frac{1}{5}\left(\frac{x}{2a+x}\right)^5 + \dots\right]$$

$$(a > 0,\ -a < x < +\infty)$$

TRIGONOMETRIC

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \cdots$$

$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \cdots$$

$$\tan x = x + \frac{x^3}{3} + \frac{2x^5}{15} + \frac{17x^7}{315} + \frac{62x^9}{2835} + \cdots \qquad \left(x^2 < \frac{\pi^2}{4}\right)$$

$$\sin^{-1} x = x + \frac{x^3}{6} + \frac{1}{2}\cdot\frac{3}{4}\cdot\frac{x^5}{5} + \frac{1}{2}\cdot\frac{3}{4}\cdot\frac{5}{6}\cdot\frac{x^7}{7} + \cdots \qquad (x^2 < 1)$$

$$\tan^{-1} x = x - \tfrac{1}{3}x^3 + \tfrac{1}{5}x^5 - \tfrac{1}{7}x^7 + \cdots \qquad (x^2 < 1)$$

$$= \frac{\pi}{2} - \frac{1}{x} + \frac{1}{3x^3} - \frac{1}{5x^5} + \cdots \qquad (x^2 > 1)$$

$$\log_e \sin x = \log_e x - \frac{x^2}{6} - \frac{x^4}{180} - \frac{x^6}{2835} - \cdots \qquad (x^2 < \pi^2)$$

$$\log_e \cos x = -\frac{x^2}{2} - \frac{x^4}{12} - \frac{x^6}{45} - \frac{17x^8}{2520} - \cdots \qquad \left(x^2 < \frac{\pi^2}{4}\right)$$

$$\log_e \tan x = \log_e x + \frac{x^2}{3} + \frac{7x^4}{90} + \frac{62x^6}{2835} + \cdots \qquad \left(x^2 < \frac{\pi^2}{4}\right)$$

$$e^{\sin x} = 1 + x + \frac{x^2}{2!} - \frac{3x^4}{4!} - \frac{8x^5}{5!} - \frac{3x^6}{6!} + \frac{56x^7}{7!} + \cdots$$

$$e^{\cos x} = e\left(1 - \frac{x^2}{2!} + \frac{4x^4}{4!} - \frac{31x^6}{6!} + \cdots\right)$$

$$e^{\tan x} = 1 + x + \frac{x^2}{2!} + \frac{3x^3}{3!} + \frac{9x^4}{4!} + \frac{37x^5}{5!} + \cdots \qquad \left(x^2 < \frac{\pi^2}{4}\right)$$

FOURIER SERIES

If $f(x) = \frac{a_0}{2} + a_1 \cos \frac{2\pi x}{T} + a_2 \cos \frac{4\pi x}{T} + \cdots$

$$+ a_m \cos \frac{2\pi m x}{T} + \cdots + b_1 \sin \frac{2\pi x}{T} + b_2 \sin \frac{4\pi x}{T}$$

$$+ b_3 \sin \frac{6\pi x}{T} + \cdots + b_n \sin \frac{2\pi n x}{T} + \cdots,$$

where

$a_0 = \frac{2}{T} \int_c^{c+T} f(x) dx, \quad a_m = \frac{2}{T} \int_c^{c+T} f(x) \cos \frac{2\pi m x}{T} dx,$ $b_n = \frac{2}{T} \int_c^{c+T} f(x) \sin \frac{2\pi n x}{T} dx,$ and $f(x + T) = f(x)$, with c and T constants.

VECTOR ANALYSIS

Definitions

Any quantity which is completely determined by its magnitude is called a *scalar*. Examples of such are mass, density, temperature, etc. Any quantity which is completely determined by its magnitude and direction is called a *vector*. Examples of such are velocity, acceleration, force, etc. A vector quantity is represented by a directed line segment, the length of which represents the magnitude of the vector. A vector quantity is usually represented by a bold-faced letter such as $\mathbf{V}$. Two vectors $\mathbf{V}_1$ and $\mathbf{V}_2$ are equal to one another if they have equal magnitudes and are acting in the same directions. A negative vector, written as $-\mathbf{V}$ is one which acts in the opposite direction to $\mathbf{V}$, but is of equal magnitude to it. If we represent the magnitude of $\mathbf{V}$ by v, we write $|\mathbf{V}| = v$. A vector parallel to $\mathbf{V}$, but equal to the reciprocal of its magnitude is written as $\mathbf{V}^{-1}$ or as $\frac{1}{\mathbf{V}}$.

The unit vector $\frac{\mathbf{V}}{|\mathbf{V}|}$ $(\mathbf{V} \neq 0)$ is the one which has the same direction as $\mathbf{V}$, but has a magnitude of 1.

Vector Algebra

The vector sum of $\mathbf{V}_1$ and $\mathbf{V}_2$ is represented by $\mathbf{V}_1 + \mathbf{V}_2$. The vector sum of $\mathbf{V}_1$ and $-\mathbf{V}_2$, or the difference of the vector $\mathbf{V}_2$ from $\mathbf{V}_1$ is represented by $\mathbf{V}_1 - \mathbf{V}_2$.

If r is a scalar, then $r\mathbf{V} = \mathbf{V}r$, and represents a vector r times the magnitude of $\mathbf{V}$, in the same direction as $\mathbf{V}$ if r is positive, and in the opposite direction if r is negative. If r and s are scalars, $\mathbf{V}_1$, $\mathbf{V}_2$, $\mathbf{V}_3$, vectors, then the following rules of scalars and vectors hold:

$$\mathbf{V}_1 + \mathbf{V}_2 = \mathbf{V}_2 + \mathbf{V}_1$$
$$(r + s)\mathbf{V}_1 = r\mathbf{V}_1 + s\mathbf{V}_1; \qquad r(\mathbf{V}_1 + \mathbf{V}_2) = r\mathbf{V}_1 + r\mathbf{V}_2$$
$$\mathbf{V}_1 + (\mathbf{V}_2 + \mathbf{V}_3) = (\mathbf{V}_1 + \mathbf{V}_2) + \mathbf{V}_3 = \mathbf{V}_1 + \mathbf{V}_2 + \mathbf{V}_3$$

If $\mathbf{V}_1$ is a vector in space, and a_1, b_1, c_1, the respective magnitudes of the projections of the vector along the coordinate Ox, Oy, Oz axes, then

$\mathbf{V}_1 = a_1\mathbf{i} + b_1\mathbf{j} + c_1\mathbf{k}$, where $\mathbf{i}$, $\mathbf{j}$, $\mathbf{k}$ are respectively the unit vectors along Ox, Oy, and Oz. Its magnitude is

$$|\mathbf{V}_1| = \sqrt{a_1^2 + b_1^2 + c_1^2},$$

and its direction cosines satisfy the proportion

$$a_1 : b_1 : c_1 = \cos\alpha : \cos\beta : \cos\gamma.$$

Thus, if $\mathbf{V}_1 = a_1\mathbf{i} + b_1\mathbf{j} + c_1\mathbf{k}$ and $\mathbf{V}_2 = a_2\mathbf{i} + b_2\mathbf{j} + c_2\mathbf{k}$,
Then $\mathbf{V}_1 + \mathbf{V}_2 = (a_1 + a_2)\mathbf{i} + (b_1 + b_2)\mathbf{j} + (c_1 + c_2)\mathbf{k}$

VECTOR ANALYSIS (Continued)

The Scalar, Dot, or Inner Product of Two Vectors $\mathbf{V}_1$ and $\mathbf{V}_2$

This product is represented as $\mathbf{V}_1 \cdot \mathbf{V}_2$ and is defined to be equal to $|\mathbf{V}_1|\,|\mathbf{V}_2| \cos \theta$, where θ is the angle from $\mathbf{V}_1$ to $\mathbf{V}_2$, i.e.,

$$\mathbf{V}_1 \cdot \mathbf{V}_2 = |\mathbf{V}_1|\,|\mathbf{V}_2| \cos \theta$$

The following rules apply for this product:

$$\mathbf{V}_1 \cdot \mathbf{V}_2 = a_1a_2 + b_1b_2 + c_1c_2 = \mathbf{V}_2 \cdot \mathbf{V}_1$$

It should be noted that scalar multiplication is commutative.

If $\mathbf{V}_1 = \mathbf{V}_2$, then $\mathbf{V}_1 \cdot \mathbf{V}_2 = |\mathbf{V}_1|^2$

$$(\mathbf{V}_1 + \mathbf{V}_2) \cdot \mathbf{V}_3 = \mathbf{V}_1 \cdot \mathbf{V}_3 + \mathbf{V}_2 \cdot \mathbf{V}_3$$

$$\mathbf{V}_1 \cdot (\mathbf{V}_2 + \mathbf{V}_3) = \mathbf{V}_1 \cdot \mathbf{V}_2 + \mathbf{V}_1 \cdot \mathbf{V}_3$$

$$\mathbf{i} \cdot \mathbf{i} = \mathbf{j} \cdot \mathbf{j} = \mathbf{k} \cdot \mathbf{k} = 1; \qquad \mathbf{i} \cdot \mathbf{j} = \mathbf{j} \cdot \mathbf{k} = \mathbf{k} \cdot \mathbf{i} = 0$$

The Vector or Cross Product of Vectors $\mathbf{V}_1$ and $\mathbf{V}_2$

This product is represented as $\mathbf{V}_1 \times \mathbf{V}_2$ and is defined to be equal to $|\mathbf{V}_1|\,|\mathbf{V}_2|\,(\sin \theta)\mathbf{l}$, where θ is the angle from $\mathbf{V}_1$ to $\mathbf{V}_2$ and $\mathbf{l}$ is a unit vector perpendicular to the plane of $\mathbf{V}_1$ and $\mathbf{V}_2$ and so directed that a right-handed screw driven in the direction of $\mathbf{l}$ would carry $\mathbf{V}_1$ into $\mathbf{V}_2$,, i.e.,

$$\mathbf{V}_1 \times \mathbf{V}_2 = |\mathbf{V}_1|\,|\mathbf{V}_2|\,(\sin \theta)\mathbf{l}$$

The following rules apply for vector products:

$$\mathbf{V}_1 \times \mathbf{V}_2 = -\mathbf{V}_2 \times \mathbf{V}_1$$

$$\mathbf{V}_1 \times (\mathbf{V}_2 + \mathbf{V}_3) = \mathbf{V}_1 \times \mathbf{V}_2 + \mathbf{V}_1 \times \mathbf{V}_3$$

$$(\mathbf{V}_1 + \mathbf{V}_2) \times \mathbf{V}_3 = \mathbf{V}_1 \times \mathbf{V}_3 + \mathbf{V}_2 \times \mathbf{V}_3$$

$$\mathbf{V}_1 \times (\mathbf{V}_2 \times \mathbf{V}_3) = \mathbf{V}_2(\mathbf{V}_1 \cdot \mathbf{V}_3) - \mathbf{V}_3(\mathbf{V}_1 \cdot \mathbf{V}_2)$$

$$\begin{aligned}\mathbf{i} \times \mathbf{i} = \mathbf{j} \times \mathbf{j} = \mathbf{k} \times \mathbf{k} &= 0.\mathbf{l} \text{ (zero vector)} \\ &= 0\end{aligned}$$

$$\mathbf{i} \times \mathbf{j} = \mathbf{k}, \qquad \mathbf{j} \times \mathbf{k} = \mathbf{i}, \qquad \mathbf{k} \times \mathbf{i} = \mathbf{j}$$

If $\mathbf{V}_1 = a_1\mathbf{i} + b_1\mathbf{j} + c_1\mathbf{k}$, $\quad \mathbf{V}_2 = a_2\mathbf{i} + b_2\mathbf{j} + c_2\mathbf{k}$,
$\mathbf{V}_3 = a_3\mathbf{i} + b_3\mathbf{j} + c_3\mathbf{k}$,

then

$$\mathbf{V}_1 \times \mathbf{V}_2 = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \end{vmatrix} = (b_1c_2 - b_2c_1)\mathbf{i} + (c_1a_2 - c_2a_1)\mathbf{j} + (a_1b_2 - a_2b_1)\mathbf{k}$$

It should be noted that, since $\mathbf{V}_1 \times \mathbf{V}_2 = -\mathbf{V}_2 \times \mathbf{V}_1$, the vector product is not commutative.

$$\begin{aligned}\mathbf{V}_1 \cdot (\mathbf{V}_2 \times \mathbf{V}_3) = (\mathbf{V}_1 \times \mathbf{V}_2) \cdot \mathbf{V}_3 &= \mathbf{V}_2 \cdot (\mathbf{V}_3 \times \mathbf{V}_1) \\ = (\mathbf{V}_1\mathbf{V}_2\mathbf{V}_3) &= \begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix}\end{aligned}$$

which is equal to the volume of a parallelepiped whose three determining edges are $\mathbf{V}_1$, $\mathbf{V}_2$, $\mathbf{V}_3$.

Differentiation of Vectors

If $\mathbf{V}_1 = a_1\mathbf{i} + b_1\mathbf{j} + c_1\mathbf{k}$, and $\mathbf{V}_2 = a_2\mathbf{i} + b_2\mathbf{j} + c_2\mathbf{k}$, and if $\mathbf{V}_1$ and $\mathbf{V}_2$ are functions of the scalar t, then

$$\frac{d}{dt}(\mathbf{V}_1 + \mathbf{V}_2 + \cdot\cdot\cdot) = \frac{d\mathbf{V}_1}{dt} + \frac{d\mathbf{V}_2}{dt} + \cdot\cdot\cdot,$$

where $\frac{d\mathbf{V}_1}{dt} = \frac{da_1}{dt}\mathbf{i} + \frac{db_1}{dt}\mathbf{j} + \frac{dc_1}{dt}\mathbf{k}$, etc.

$$\frac{d}{dt}(\mathrm{V}_1 \cdot \mathbf{V}_2) = \frac{d\mathbf{V}_1}{dt} \cdot \mathbf{V}_2 + \mathbf{V}_1 \cdot \frac{d\mathbf{V}_2}{dt}$$

$$\frac{d}{dt}(\mathbf{V}_1 \times \mathbf{V}_2) = \frac{d\mathbf{V}_1}{dt} \times \mathbf{V}_2 + \mathbf{V}_1 \times \frac{d\mathbf{V}_2}{dt}$$

Differential Operators—Rectangular Coordinates

By definition

$$\nabla \equiv \text{del} \equiv \mathbf{i}\frac{\delta}{\delta x} + \mathbf{j}\frac{\delta}{\delta y} + \mathbf{k}\frac{\delta}{\delta z}$$

$$\nabla^2 \equiv \text{Laplacian} \equiv \frac{\delta^2}{\delta x^2} + \frac{\delta^2}{\delta y^2} + \frac{\delta^2}{\delta z^2}$$

If S is a scalar function, then

$$\nabla S \equiv \text{grad } S \equiv \frac{\delta S}{\delta x}\mathbf{i} + \frac{\delta S}{\delta y}\mathbf{j} + \frac{\delta S}{\delta z}\mathbf{k}$$

The *distributive* law holds for finding a gradient. Thus if S and T are scalar functions

$$\nabla(S + T) = \nabla S + \nabla T$$

The *associative* law becomes the rule for differentiating a product:

$$\nabla(ST) = S\nabla T + T\nabla S$$

If $\mathbf{V}$ is a vector function with the magnitudes of the components parallel to the three coordinate axes V_x, V_y, V_z, then

$$\nabla \cdot \mathbf{V} \equiv \text{div } \mathbf{V} \equiv \frac{\delta V_x}{\delta x} + \frac{\delta V_y}{\delta y} + \frac{\delta V_z}{\delta z}$$

The divergence obeys the distributive law. Thus, if **V** and **U** are vector functions, then

$$\nabla \cdot (\mathbf{V} + \mathbf{U}) = \nabla \cdot \mathbf{V} + \nabla \cdot \mathbf{U}$$

$$\nabla \times \mathbf{V} \equiv \text{curl } \mathbf{V} \equiv \text{rot } \mathbf{V} \equiv \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \dfrac{\delta}{\delta x} & \dfrac{\delta}{\delta y} & \dfrac{\delta}{\delta z} \\ V_x & V_y & V_z \end{vmatrix}$$

The operator ∇ can be used more than once. The number of possibilities where ∇ is used twice are

$$\begin{aligned} \nabla \cdot (\nabla\theta) &\equiv \text{div grad } \theta \\ \nabla \times (\nabla\theta) &\equiv \text{curl grad } \theta \\ \nabla(\nabla \cdot \mathbf{V}) &\equiv \text{grad div } \mathbf{V} \\ \nabla \cdot (\nabla \times \mathbf{V}) &\equiv \text{div curl } \mathbf{V} \\ \nabla \times (\nabla \times \mathbf{V}) &\equiv \text{curl curl } \mathbf{V} \end{aligned}$$

Thus: $\text{div grad } S \equiv \nabla \cdot (\nabla S) \equiv \text{Laplacian } S \equiv \nabla^2 S$

$$\equiv \frac{\delta^2 S}{\delta x^2} + \frac{\delta^2 S}{\delta y^2} + \frac{\delta^2 S}{\delta z^2}$$

$$\text{curl grad } S \equiv 0; \qquad \text{curl curl } \mathbf{V} \equiv \text{grad div } \mathbf{V} - \nabla^2\mathbf{V};$$

$$\text{div curl } \mathbf{V} \equiv 0$$

Green's Theorem

Let **F** be a vector function and v a volume bounded by a surface s, then

$$\iiint_{(v)} \text{div } \mathbf{F} = \iiint_{(v)} \nabla \cdot \mathbf{F}\, dv = \iint_{(s)} \mathbf{F} \cdot ds,$$

where the integrations are to be carried out over the volume v and the surface s.

Stokes Theorem

Let **F** be a vector function and s a surface bounded by a simple closed curve c, then

$$\int_{(c)} \mathbf{F} \cdot d\,\mathbf{1} = \iint_{(s)} (\nabla \times \mathbf{F}) \cdot ds = \iint_{(s)} \text{curl } \mathbf{F} \cdot ds,$$

where the integrations are to be carried out over the curve c and the surface s. It should be noted that

$$d\,\mathbf{1} = dx\,\mathbf{i} + dy\,\mathbf{j} + dz\,\mathbf{k}$$

The theorem implies that the line integral of **F** over the contour c equals the surface integral of $\nabla \times \mathbf{F}$ over a surface s which is bounded by c.

MISCELLANEOUS

The Sum (Σ, = Sigma) and Product (Π, = Pi) Notations

Σ denotes the sum, and Π, the product of all quantities of a given collection. In particular,

$$\sum_{i=m}^{m+n} x_i \text{ means } x_m + x_{m+1} + \ldots + x_{m+n}, \ (n+1 \text{ terms in all}),$$

$$\prod_{i=m}^{m+n} x_i \text{ means } x_m x_{m+1} \ldots x_{m+n}, \ (n+1 \text{ factors in all}).$$

For indicated **range**, R, (such as $m \leqq i \leqq m+n$), one may write $\sum\limits_R x_i$, $\prod\limits_R x_i$, respectively. Where the range is clear from the context one writes Σx_i, Πx_i, or even Σx, Πx, respectively. For c a constant and for x_i and y_i with common range (say of n elements),

$$\Sigma c x_i = c\Sigma x_i, \ \Sigma(x_i + y_i) = \Sigma x_i + \Sigma y_i, \ \Sigma(x_i + c) = nc + \Sigma x_i.$$

Special Numerical Relations

(i) For range, $i = 1, 2, \ldots, n$, with $x_i = i$.
$\Sigma x_i = n(n+1)/2$, $\Sigma(2x_i - 1) = n^2$,
$\Sigma x_i^2 = n(n+1)(2n+1)/6$.
$\Sigma x_i^3 = (\Sigma x_i)^2$, $\Sigma x_i^4 = (\Sigma x_i^2)[6(\Sigma x_i) - 1]/5$.
$\Pi(c + 1 - x_i) = c^{(n)}$, $\Pi x_i = n^{(n)} = n!$ ("factorial n").
Hence $n! = n\,.\,(n-1)!$ $0!$ is defined to be 1.
Stirling's formula (used for n large),

$$\sqrt{2n\pi}(n/e)^n < n! < \sqrt{2n\pi}(n/e)^n\left(1 + \frac{1}{12n-1}\right).$$

$$(\pi = 3.14159\ldots, e = 2.71828\ldots).$$

$n!/(n-m)!$ gives the number of **permutations** of n distinct things taken m at a time.

(ii) For range, $i = -\left(\frac{n-1}{2}\right), -\left(\frac{n-1}{2}\right) + 1, \ldots, \left(\frac{n-1}{2}\right) - 1, \left(\frac{n-1}{2}\right)$, with $x_i = i$ (whether n is odd or even),

$$\sum x_i = \sum x_i^3 = 0, \ \sum x_i^2 = \frac{n(n^2-1)}{12}, \ \sum x_i^4 = \frac{3n^2-7}{20}\sum x_i^2.$$

(iii) **The Binomial Coefficients, $\binom{n}{m}$.**

$\binom{n}{m} = n!/[(n-m)!m!]$, for integers m, n, $0 \leqq m \leqq n$. $\binom{n}{0} = \binom{n}{n} = 1$.

$(x + c)^n = \sum\limits_r \binom{n}{r} x^{n-r} c^r$, $(0 \leqq r \leqq n)$, the **binomial expansion.** $\binom{n}{m}$ gives also the number of **combinations of n distinct things taken m at a time.**

$\binom{n}{m} + \binom{n}{m+1} = \binom{n+1}{m+1}$, **recursion relation** for binomial coefficients.

$$\binom{n}{n-m} = \binom{n}{m},\ \sum_r (-1)^r \binom{n}{r} = 0,\ \sum_r \binom{n}{r}^2 = \binom{2n}{n},\ \sum_{s=m}^{n} \binom{s}{m} = \binom{n+1}{m+1}$$

Table of Binomial Coefficients

n	$\binom{n}{0}$	$\binom{n}{1}$	$\binom{n}{2}$	$\binom{n}{3}$	$\binom{n}{4}$	$\binom{n}{5}$	$\binom{n}{6}$	$\binom{n}{7}$	$\binom{n}{8}$	$\binom{n}{9}$	$\binom{n}{10}$
0	1										
1	1	1									
2	1	2	1								
3	1	3	3	1							
4	1	4	6	4	1						
5	1	5	10	10	5	1					
6	1	6	15	20	15	6	1				
7	1	7	21	35	35	21	7	1			
8	1	8	28	56	70	56	28	8	1		
9	1	9	36	84	126	126	84	36	9	1	
10	1	10	45	120	210	252	210	120	45	10	1
11	1	11	55	165	330	462	462	330	165	55	11
12	1	12	66	220	495	792	924	792	495	220	66
13	1	13	78	286	715	1287	1716	1716	1287	715	286
14	1	14	91	364	1001	2002	3003	3432	3003	2002	1001
15	1	15	105	455	1365	3003	5005	6435	6435	5005	3003
16	1	16	120	560	1820	4368	8008	11440	12870	11440	8008
17	1	17	136	680	2380	6188	12376	19448	24310	24310	19448
18	1	18	153	816	3060	8568	18564	31824	43758	48620	43758
19	1	19	171	969	3876	11628	27132	50388	75582	92378	92378
20	1	20	190	1140	4845	15504	38760	77520	125970	167960	184756

NOTE: $\binom{n}{m} = \dfrac{n(n-1)(n-2)\ldots(n-m+1)}{m(m-1)(m-2)\ldots 3.2.1}$; $\binom{n}{0} = 1$; $\binom{n}{1} = n$.

For coefficients missing from the above table, use the relation

$\binom{n}{m} = \binom{n}{n-m}$, e.g. $\binom{20}{11} = \binom{20}{9} = 167960$.

Finite Differences

For equi-spaced arguments x_i, and associated y_i, the successive advancing y-differences are, $\Delta^0 y_i = y_i$, $\Delta y_i = y_{i+1} - y_i$, $\Delta^2 y_i = \Delta y_{i+1} - \Delta y_i = y_{i+2} - 2y_{i+1} + y_i, \ldots,$ $\Delta^m y_i = \Delta^{m-1} y_{i+1} - \Delta^{m-1} y_i = \sum_r (-1)^r \binom{m}{r} y_{i+m-r}$. With arbitrary origin A and class-interval length, $x_{i+1} - x_i = h$, using $u_i = (x_i - A)/h$, write $y(u_i)$ for y_i. Then if for some fixed m, for the portion of the table considered, the values of $\Delta^{m+1} y_i$ be zero (or approximately, if these be regarded as negligible) **Newton's formula** gives

$$y(u) = \sum \frac{u^{(r)}}{r!} \Delta^r y(0) = y(0) + u\Delta y(0) + \frac{u(u-1)}{1 \cdot 2} \Delta^2 y(0) + \cdots + \frac{u(u-1)\ldots(u-m+1)}{m!} \Delta^m y(0).$$

This formula reduces to an identity for $u = u_0, u_1, \ldots, u_n$, $(u_i = i)$, and may be used to interpolate for intermediate values.

Example. Given

x	−4,	−2,	0,	2,	4,	6,	8, . . .
y	10,	14,	30,	64,	122,	210,	334, . . .

to find a value for y when $x = 10$, and when $x = 1$. Suppose for some reason A has been taken at $x = 2$. The work may be arranged as follows:

u	x	y	Δ	Δ^2	Δ^3	Δ^4
−3	−4	10				
			4			
−2	−2	14		12		
			16		6	
−1	0	30		18		0
			34		6	
0	2	64		24		0
			58		6	
1	4	122		30		0
			88		6

			—		—	
—	—	—		—		—

$$y(u) = 64 + 58u + 30\frac{u(u-1)}{1 \cdot 2} + 6\frac{u(u-1)(u-2)}{1 \cdot 2 \cdot 3}$$
$$= 64 + 58u + 15u(u-1) + u(u-1)(u-2).$$

At $x = 10$, $u = 4$. Substituting $u = 4$, one has $y|_{x=10} = 500$.
At $x = 1$, $u = -\frac{1}{2}$. Substituting $u = -\frac{1}{2}$, one has $y|_{x=1} = 44\frac{3}{8}$

STATISTICS

Central Measures

Here the range of i is from 1 to n. With each value x_i is associated a weighting factor $f_i \geq 0$ (such as the frequency, the probability, the mass, the reliability, or other multiplier).

N, **the total weight,** $= \Sigma f_i$.

$\bar{x}$, **the arithmetic mean,** $= \Sigma f_i x_i / N = \Sigma f_i x_i / \Sigma f_i$.

GM, **the geometric mean** (available when each x_i is positive), $= \sqrt[N]{\Pi x_i^{f_i}}$. $\text{Log } GM = \Sigma f_i \log x_i / N$.

Mo, **the mode,** = value among $(x_1, \ldots, x_n)$ having maximum associated f_i (usually obtained by interpolating after the data are graduated). For unweighted items, x_i, a mode is a value about which the values of x_i cluster most densely.

RMS, **the root-mean-square,** $= \sqrt{\Sigma f_i x_i^2 / N}$.

Md, **the median** (see below). For unweighted items, the median is the value, equaled or exceeded by exactly half of the values x_i in the given list. In case of a central pair, the median is usually taken as the arithmetic mean of this pair.

Mm, **the mid-mean** (see below). For unweighted items, the mid-mean is the arithmetic mean of the half-list obtained upon dropping out the highest quarter and lowest quarter of the items.

Cum $f|_X$, the value of "cumulative f" at X, $= \sum_{x_i < X} f_i$ (interpolation being used for X if necessary).

The M-Tiles

For **ungrouped data,** X is called the **rth m-tile** (or **rth m-tile mark**) $(r = 0, 1, \ldots, m)$ if simultaneously, $\sum_{x_i < X} f_i/N \leq r/m$, and $\sum_{x_i > X} f_i/N \leq (m - r)/m$. In particular the zeroth m-tile is **min,** the minimal value among the list $(x_1, \ldots, x_n)$, and the mth m-tile is **max,** the maximal value among the list.

For **grouped data,** the rth m-tile mark, X, is such that

$$\text{Cum } f|_X = Nr/m, \ (r = 0, 1, 2, \ldots, m).$$

$$\text{Cum } f|_{\min} = 0, \qquad \text{Cum } f|_{\max} = N.$$

In particular, certain intermediate $(0 < r < m)$ m-tile **marks** are named as follows:

m	$r = 1$	2	3	. . .
2	Md (median)			
3	T_1 (lower tertile)	T_2 (upper tertile)		
4	Q_1 (lower quartile)	Md	Q_3 (upper quartile)	
10	D_1 (first decile)	D_2	D_3	etc.
100	PC_1 (first percentile)	PC_2	PC_3	etc.

The term "rth m-tile" ($r = 1, \ldots, m$) is also used to denote the class interval extending from the $(r-1)$st to rth m-tile mark as defined above.

Mm, **the mid-mean,** =

$$2 \sum_{Q_1 \le x_i \le Q_3} f_i x_i / N = \sum_{Q_1 \le x_i \le Q_3} f_i x_i \Big/ \sum_{Q_1 \le x_i \le Q_3} f_i .$$

When each x_i is positive, and not all are equal, one always has $0 < \min < GM < \bar{x} < RMS < \max$.

For moderately-skewed distributions, one has approximately $Mo - \bar{x} = 3(Md - \bar{x})$, or $3Md = Mo + 2\bar{x}$.

Measures of Dispersion and Skewness

Here A is an arbitrary reference value, usually a convenient integral measure near $\bar{x}$.

ν_k, **kth moment about A,** $= \Sigma f_i (x_i - A)^k / N$, $(k = 0, 1, \ldots)$.

$\nu_0 = 1$, $\nu_1 = \bar{x} - A$. ν_2 as function of A is minimum for $A = \bar{x}$.

μ_k, **kth moment about $\bar{x}$,** $= \Sigma f_i (x_i - \bar{x})^k / N$, $(k = 0, 1, \ldots)$.

$$\begin{aligned}
\mu_0 &= 1, \\
\mu_1 &= 0, \\
\mu_2 &= \nu_2 - \nu_1^2 \ (\mu_2 = \text{variance}), \\
\mu_3 &= \nu_3 - 3\nu_1\nu_2 + 2\nu_1^3, \\
\mu_4 &= \nu_4 - 4\nu_1\nu_3 + 6\nu_1^2\nu_2 - 3\nu_1^4. \\
\beta_1 &= \mu_3^2/\mu_2^3,\ \beta_2 = \mu_4/\mu_2^2.
\end{aligned}$$

σ, **standard deviation,** $= \sqrt{\mu_2}$.

$\alpha_3/2$, **momental skewness;** $\alpha_3 = \sqrt{\beta_1} = \mu_3/\sigma^3$.

$(\alpha_4 - 3)/2$, **kurtosis;** $\alpha_4 = \beta_2$.

MD, **mean deviation** (from the mean), $= \Sigma f_i |x_i - \bar{x}| / N$

$$= 2\left[\bar{x} \sum_{x_i < \bar{x}} f_i - \sum_{x_i < \bar{x}} f_i x_i \right] / N.$$

(This latter form is convenient for computation.)

s, **quartile deviation,** $= |Q_3 - Q_1|/2$.

$P.E.$, **probable error,** $= 0.6745\sigma$.

V, **coefficient of variation,** $= 100\sigma/\bar{x}\,\%$.

Pearson's measure of skewness $= (\bar{x} - Mo)/\sigma$. (Usually approximately $\alpha_3/2$.)

Bowley's measure of skewness $= (Q_3 - 2Md + Q_1)/(2s)$. (Bowley's measure of skewness lies between -1 and $+1$.)

The Class Interval

$$\Delta x_i = x_{i+1} - x_i.$$

For equi-spaced arguments, $\Delta x_i = h$, the **length of the class interval,** x_i is the mid-value or **class mark.** The interval from $x_i - (h/2)$ to $x_i + (h/2)$ is the **class interval** with these as given **initial** and **terminal end values.**

$$\begin{aligned} u_i &= (x_i - A)/h. \\ \bar{u} &= \Sigma f_i u_i/N,\ \bar{x} = h\bar{u} + A. \\ (\mu_k)_x &= h^k(\mu_k)_u,\ (k = 0, 1, \ldots). \\ \sigma_u{}^2 &= [\Sigma f_i u_i{}^2/N] - \bar{u}^2,\ \sigma_x = h\sigma_u. \\ (\beta_1)_x &= (\beta_1)_u,\ (\beta_2)_x = (\beta_2)_u. \end{aligned}$$

Sheppard's corrections (to correct approximately for the error due to treating all elements in a given class interval of length h as though concentrated at the class mark).

For μ_0, μ_1, μ_3, no corrections.

In x-units,

corrected $(\mu_2)_x$ = uncorrected $(\mu_2)_x - h^2/12$,

corrected $(\mu_4)_x$ = uncorrected $(\mu_4)_x - h^2$ uncorrected $(\mu_2)_x/2 + 7h^4/240$.

In u-units, replace h by 1 in the formulae given above.

Least Squares

The **normal equations** for finding coefficients, $a_0, a_1, \ldots, a_m$, in fitting a curve of the form $y = a_0 + a_1x + \ldots + a_mx^m$ to data (X_i, Y_i), $i = 1, \ldots, n$, $(n > m)$, are $m + 1$ in number as follows:

$$\begin{aligned} \Sigma Y_i &= a_0n + a_1\Sigma X_i + a_2\Sigma X_i{}^2 + \ldots + a_m\Sigma X_i{}^m, \\ \Sigma X_iY_i &= a_0\Sigma X_i + a_1\Sigma X_i{}^2 + a_2\Sigma X_i{}^3 + \ldots + a_m\Sigma X_i{}^{m+1}, \\ &\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots \\ \Sigma X_i{}^mY_i &= a_0\Sigma X_i{}^m + a_1\Sigma X_i{}^{m+1} + a_2\Sigma X_i{}^{m+2} + \ldots + a_m\Sigma X_i{}^{2m}. \end{aligned}$$

Deviation from fitted curve,

$$d_i = Y_i - (a_0 + a_1X_i + \ldots + a_mX_i{}^m).$$

$$\Sigma d_i{}^2 = \Sigma Y_i{}^2 - (a_0\Sigma Y_i + a_1\Sigma X_iY_i + \ldots + a_m\Sigma X_i{}^mY_i).$$

For $z = ab^x$, use $y = \log z$, $a_0 = \log a$, $a_1 = \log b$.

For $z = at^p$, use $y = \log z$, $a_0 = \log a$, $a_1 = p$, $x = \log t$.

S_y, **standard error of estimate,** = root-mean-square of the y-deviations about a fitted curve $= \sqrt{\Sigma d_i{}^2/n}$.

Simple Correlation

Product Moment Method

Given n equi-spaced measurements X_i, $i = 1, 2, \ldots, n$, with $h = X_{i+1} - X_i$, $x_i = X_i - \bar{X}$; and m equi-spaced measurements Y_j, $j = 1, 2, \ldots, m$, with $k = Y_{j+1} - Y_j$, $y_j = Y_j - \bar{Y}$; and a weight (frequency, probability, etc.) e_{ij} (≥ 0), associated with (X_i, Y_j). Here e_{ij} is an entry in the table.

$$f_i = \sum_j e_{ij},\ g_j = \sum_i e_{ij}.$$

$$N = \sum_{ij} e_{ij} = \sum_i f_i = \sum_j g_j. \quad \text{(Check)}$$

$$\bar{x} = \sum_{ij} e_{ij}X_i/N = \sum_i f_iX_i/N;\ \bar{y} = \sum_{ij} e_{ij}Y_j/N = \sum_j g_jY_j/N.$$

Let A and B be arbitrary reference values, usually convenient integral measures near $\bar{X}$ and $\bar{Y}$, respectively.

$$u_i = (X_i - A)/h,\ v_j = (Y_j - B)/k;$$

$$\bar{u} = \Sigma f_iu_i/N,\ \bar{X} = h\bar{u} + A,\ \bar{v} = \Sigma g_jv_j/N,\ \bar{Y} = k\bar{v} + B.$$

$$\left.\begin{aligned}\sigma_u^2 &= (\mu_2)_u = (\Sigma f_iu_i^2/N) - \bar{u}^2,\ \sigma_x = h\sigma_u.\\ \sigma_v^2 &= (\mu_2)_v = (\Sigma g_jv_j^2/N) - \bar{v}^2,\ \sigma_y = k\sigma_v.\end{aligned}\right\} \text{Apply Sheppard's corrections.}$$

$$U_j = \sum_i e_{ij}u_i,\ V_i = \sum_j e_{ij}v_j,\ P = \sum u_iV_i = \sum v_jU_j. \quad \text{(Check)}$$

$$p_{uv} = \sum_{ij} e_{ij}(u_i - \bar{u})(v_j - \bar{v})/N$$

$$= (P/N) - \bar{u}\bar{v}.$$

$$p_{xy} = hkp_{uv}.$$

$r = p_{uv}/(\sigma_u\sigma_v) = p_{xy}/(\sigma_x\sigma_y)$ **(product-moment) coefficient of correlation.** In every case $-1 \leq r \leq 1$.

$Y - \bar{Y} = r\dfrac{\sigma_y}{\sigma_x}(X - \bar{X})$, or $y = r\dfrac{\sigma_y}{\sigma_x}x$, **regression line of y on x.**

$X - \bar{X} = r\dfrac{\sigma_x}{\sigma_y}(Y - \bar{Y})$, or $x = r\dfrac{\sigma_x}{\sigma_y}y$, **regression line of x on y.**

Example of Computation for Product-Moment Coefficient of Correlation

	u_i	−3	−2	−1	0	1	2	g_j	g_jv_j	$g_jv_j^2$	U_j $\left(=\sum_i e_{ij}u_i\right)$	v_jU_j
v_j	y_j \ x_i	12	16	20	24	28	32					
2	21			1	5	7	1	14	28	56	8	16
1	18		1	3	7	5	2	18	18	18	4	4
0	15		2	3	4	1		10	0	0		0
−1	12		3	1	1			5	−5	5	−7	7
−2	9	2	1					3	−6	12	−8	16
f_i		2	7	8	17	13	3	50	35	91		43
f_iu_i		−6	−14	−8	0	13	6	−9				
$f_iu_i^2$		18	28	8	0	13	12	79				
$V_i \left(=\sum_j e_{ij}v_j\right)$		−4	−4	4		19	4					
u_iV_i		12	8	−4	0	19	8	43				

$A = 24,\ B = 15,$
$h = 4,\ k = 3,$
$N = \Sigma f_i = \Sigma g_j = 50,$
$\Sigma f_iu_i = -9,\ \Sigma g_jv_j = 35,$
$\Sigma f_iu_i^2 = 79,\ \Sigma g_jv_j^2 = 91,$
$P = \Sigma u_iV_i = \Sigma v_jU_j = 43.$

$\bar{u} = -9/50 = -.18 \quad \bar{v} = 35/50 = .70$

$\sigma_u^2 = (79/50) - (-.18)^2 - .083 = 1.46, \quad \sigma_u = 1.21$

$\sigma_v^2 = (91/50) - (.70)^2 - .083 = 1.247. \quad \sigma_v = 1.117$

$p_{uv} = (43/50) - (-.18)(.70) = +0.986$

$r = +0.986/(1.21 \times 1.117) = +.730 \quad$ Ans. $r = +.730$

RANK DIFFERENCE METHOD

Given n corresponding pairs of measured items (X_i, Y_i), $(i = 1, \ldots, n)$. Let (u_i, v_i) be the corresponding rank numbers. Here $u_i = 1$ for the largest X_i, 2 for the next largest X_i, etc., and similarly $v_i = 1$ for the largest Y_i, 2 for the next largest Y_i, etc. $\rho = 1 - \dfrac{6\Sigma(u_i - v_i)^2}{n(n^2 - 1)}$, (rank difference) **coefficient of correlation.** In every case $-1 \leq \rho \leq 1$. Check: $\Sigma(u_i - v_i) = 0$.

Example of Computation for Rank-Difference Coefficient of Correlation

X_i	Y_i	u_i	v_i	$u_i - v_i$	$(u_i - v_i)^2$	
76	52	3	1	+2	4	Check: $\Sigma(u_i - v_i) = 0$.
66	34	8	9	−1	1	
63	32	10	10	0	0	
74	45	4	4	0	0	$\rho = 1 - \dfrac{6 \times 62}{10(10^2 - 1)}$
79	50	1	2	−1	1	
69	37	7	7	0	0	
77	35	2	8	−6	36	$= +0.63$
65	42	9	5	+4	16	
71	40	6	6	0	0	Ans. $\rho = +.63$
73	48	5	3	+2	4	
$N = 10$				0	62	

Probability

If among $a + b$ equi-probable and mutually exclusive events, a are regarded as favorable and b unfavorable, then for a single trial

p, probability of favorable outcome, $= \dfrac{a}{a + b}$,

q, probability of unfavorable outcome, $= 1 - p = \dfrac{b}{a + b}$.

The successive terms in the binomial expansion $(p + q)^n = \sum_r \binom{n}{r} p^{n-r} q^r$ give the respective probabilities that in n trials, the event will be favorable exactly $n - r$ times, $r = 0, \ldots, n$.

The mean number of favorable events is np, of unfavorable, nq; the standard deviation is $\sigma = \sqrt{npq}$, $\alpha_3 = (p - q)/\sigma$ (the positive direction being that of increasing unfavorability).

Normal curve (x measured in σ-units from the mean, and with area = 1):

$$y = \frac{1}{\sqrt{2\pi}} e^{-x^2/2} = 0.3989 e^{-x^2/2}.$$

STATISTICS (Continued)

MD (mean deviation from the mean) $= \sigma\sqrt{2/\pi} = 0.7979\sigma$.
s (quartile deviation from the mean) $= 0.6745\sigma = 0.845\ MD$.

Percentage areas, under normal curve, for successive class intervals measured from the mean:

Multiples of σ: 34 %, 14 %, 2 %.
Multiples of s: 25 %, 16 %, 7 %, 2 %.

Normal surface (x measured in σ_x-units y in σ_y-units from their means),

$$z = \frac{1}{2\pi\sqrt{1 - r^2}} e^{-(x^2 - 2rxy + y^2)/[2(1-r^2)]}.$$

***Goodness of Fit.** For a universe of objects falling into n mutually exclusive classes with class marks, $x_i (i = 1, 2, \ldots, n)$, let p_i be the probability for the ith class. Given a sample of N items, with f_i items in the ith class ($\Sigma f_i = N$), the probability that a random sample of N items gives no better fit, expressed in terms of n and χ^2 ("Chi square"), $= \Sigma(f_i - Np_i)^2/(Np_i)$, is given by a table, portions of which are as follows:

Probability that a Random Sample Gives no Better Fit

n \ χ^2	1	2	3	4	6	8	10	15	20
3	.607	.368	.223	.135	.050	.018	.007	.001	.000

MENSURATION FORMULÆ

Plane Figures Bounded by Straight Lines

The **area of a triangle** whose base is b and altitude h

$$= \frac{hb}{2}.$$

The area of a **triangle** with angles A, B, and C and sides opposite a, b, and c, respectively

$$= \tfrac{1}{2}ab \sin C.$$

or $$= \sqrt{s(s-a)(s-b)(s-c)},$$
where $s = \frac{1}{2}(a+b+c)$.

A **rectangle** with sides a and b has an area $= ab$.

The area of a **parallelogram** with side b and the perpendicular distance to the parallel side h

$$= bh.$$

The area of a **parallelogram** with sides a and b and the included angle θ

$$= ab \sin \theta.$$

The area of a **rhombus** with diagonals c and d,

$$= \tfrac{1}{2}cd.$$

The area of a **trapezoid** whose parallel sides are a and b and altitude h

$$= \tfrac{1}{2}(a+b)h.$$

The area of any **quadrilateral** with diagonals a and b and the angle between them θ

$$= \tfrac{1}{2}ab \sin \theta.$$

The area of a **regular polygon** with n sides, each of length l,

$$= \tfrac{1}{4}nl^2 \cot \frac{180°}{n}.$$

For a regular polygon of n sides, each side of length l, the radius of the **inscribed circle**,

$$= \frac{l}{2} \cot \frac{180°}{n}.$$

The radius of the **circumscribed circle**,

$$= \frac{l}{2} \operatorname{cosec} \frac{180°}{n}.$$

MENSURATION FORMULAE (Continued)

Area, Radius of Inscribed and Circumscribed Circles for Regular Polygons

l = length of one side.

Name.	Number of sides.	Area.	Radius of inscribed circle.	Radius of circumscribed circle.

Radius of circle inscribed in any triangle, whose sides are a, b, and c, where $s = \frac{1}{2}(a + b + c)$ is given by r

$$= \frac{\sqrt{s(s-a)(s-b)(s-c)}}{s}.$$

The radius of the **circumscribed** circle is given by R

$$= \frac{abc}{4\sqrt{s(s-a)(s-b)(s-c)}}.$$

The **perimeter of a polygon inscribed in a circle** of radius , where n is the number of sides,

$$= 2nr \sin \frac{\pi}{n}. \qquad (\pi \text{ radians} = 180°)$$

The area of the **inscribed** polygon,

$$= \tfrac{1}{2}nr^2 \sin \frac{2\pi}{n}.$$

The perimeter of a polygon circumscribed about a circle of radius r, number of sides n

$$= 2nr \tan \frac{\pi}{n}.$$

The area of the **circumscribed** polygon

$$= nr^2 \tan \frac{\pi}{n}.$$

Plane Figures Bounded by Curved Lines

The **circumference of a circle** whose radius is r and diameter $d(d = 2r)$

$$= 2\pi r = \pi d. \qquad (\pi = 3.14159)$$

The **area of a circle**

$$= \pi r^2 = \tfrac{1}{4}\pi d^2 = .7854d^2.$$

The **length of an arc** of a circle for an arc of θ degrees

$$= \frac{\pi r \theta}{180}.$$

NOTE.—In this and following similar formulæ r denotes the radius of the circle, (OC, Fig. 1).

For an arc of θ radians the length s

$$= r\theta.$$

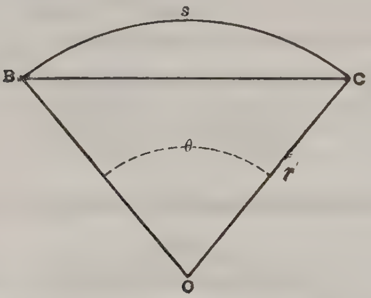

FIG. 1.

The **length of a chord** subtending an angle θ.

$$= 2r \sin \tfrac{1}{2}\theta.$$

The **area of a sector** where θ is the angle between the radii in degrees

$$= \frac{\pi r^2 \theta}{360}.$$

If s is the length of the arc, the area of the sector

$$= \frac{sr}{2}.$$

The **area of a segment** where θ is the angle between the two radii in degrees

$$= \frac{\pi r^2 \theta}{360} - \frac{r^2 \sin\theta}{2}. \qquad \left[\begin{array}{l} \theta^\circ = 180^\circ - [2 \sin^{-1}(x/r)] \\ x = \perp \text{ dist. center to chord} \end{array}\right]$$

If θ is in radians the area $= \frac{1}{2}r^2(\theta - \sin\theta)$.

The **area of the segment of a circle**

$$= \frac{\pi r^2}{2} - \left[x\sqrt{r^2 - x^2} + r^2 \operatorname{Sin}^{-1}\left(\frac{x}{r}\right)\right]$$

where r is the radius of the circle and x the perpendicular distance of the chord from the center. The principal angle must be used in this formula.

The **area of the ring** between two circles of radius r_1 and r_2, one of which encloses the other,

$$= \pi(r_1 + r_2)(r_1 - r_2).$$

The two circles are not necessarily concentric.

Area of the sector of an annulus. (Fig. 2.)—If angle $GOH = \theta$ and the lines GO and $JO = r_1$ and r_2 respectively, the area $GHIJ = \frac{1}{2}\theta(r_1 + r_2)(r_1 - r_2)$.

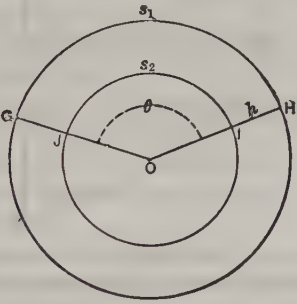

FIG. 2.

If s_1 = the length of the arc GH and s_2 = the arc JI and $h = HI = r_1 - r_2$, the area $GHIJ = \frac{1}{2}h(s_1 + s_2)$.

The **circumference of an ellipse** whose semiaxes are a and b

$= 2\pi\sqrt{\frac{a^2+b^2}{2}}$ (approx.) $= 4aE$ exactly. See tables of elliptic integrals for E, using $k = \frac{\sqrt{a^2 - b^2}}{a}$

The **area of an ellipse** $= \pi ab$.

The length of the **arc of a parabola,** as arc SPQ in Fig. 3, where $x = PR$, and $y = QR$

$$\sqrt{4x^2 + y^2} + \frac{y^2}{2x}\log_e\frac{2x + \sqrt{4x^2 + y^2}}{y}$$

The area of the section of the parabola $PQRS$, $= \frac{4}{3}xy$.

Solids Bounded by Planes

The **lateral area of a regular prism** = perimeter of a right section × the length.

The **volume of a regular prism** = area of base × the altitude.

The **lateral area of a regular pyramid,** slant height l, length of one side of base a, and a number of sides n,

$$= \tfrac{1}{2}nal.$$

The **volume of a pyramid** = $\frac{1}{3}$ area of base × altitude.

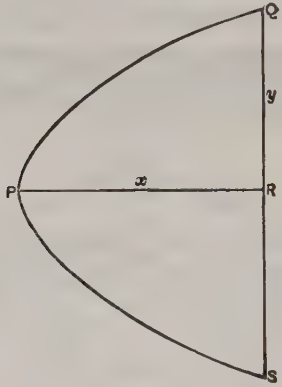

FIG. 3.

Surface and Volume of Regular Polyhedra

Surface and volume of regular polyhedra in terms of the length of one edge l.

Name.	Nature of surface.	Surface.	Volume.
Tetrahedron...	4 equilateral triangles	$1.73205l^2$	$0.11785l^3$
Hexahedron or cube........	6 squares...........	$6.00000l^2$	$1.00000l^3$
Octahedron....	8 equilateral triangles	$3.46410l^2$	$0.47140l^3$
Dodecahedron .	12 pentagons.........	$20.64573l^2$	$7.66312l^3$
Icosahedron...	20 equilateral triangles	$8.66025l^2$	$2.18170l^3$

Solids Bounded by Curved Surfaces

The **surface of a sphere** of radius r and diameter $d(= 2r)$

$$= 4\pi r^2 = \pi d^2 = 12.57r^2.$$

The **volume of a sphere**

$$= \tfrac{4}{3}\pi r^3 = \tfrac{1}{6}\pi d^3 = 4.189r^3.$$

The **area of a lune** on the surface of a sphere of radius r, included between two great circles whose inclination is θ radians.

$$= 2r^2\theta.$$

The **area of a spherical triangle** whose angles are A, B, and C (radians) on a sphere of radius r

$$= (A + B + C - \pi)r^2.$$

The **area of a spherical polygon** of n sides where θ is the sum of its angles in radians

$$= [\theta - (n - 2)\pi]r^2.$$

The area of the curved surface of a **spherical segment** of height h, radius of sphere r

$$= 2\pi\, rh.$$

The **volume of a spherical segment**, data as above

$$= \tfrac{1}{3}\pi h^2\,(3r - h).$$

If a = radius of the base of the segment, the volume

$$= \tfrac{1}{6}\pi h(h^2 + 3a^2).$$

The **curved surface of a right cylinder where** r = the radius of the base and h, the altitude,

$$= 2\pi rh.$$

The **volume of a cylinder,** data as above,

$$= \pi r^2 h.$$

The **curved surface of a right cone** whose altitude is h and radius of base r

$$= \pi r\,\sqrt{r^2 + h^2}.$$

The **volume of a cone,** data as above,

$$= \frac{\pi}{3} r^2 h = 1.047\, r^2 h.$$

The **curved surface of the frustum of a right cone,** radius of base r_1, of top r_2 and altitude h,

$$= \pi(r_1 + r_2)\,\sqrt{h^2 + (r_1 - r_2)^2}.$$

The **volume of the frustum of a cone,** data as above,

$$= \pi\,\frac{h}{3}\,(r_1^2 + r_1 r_2 + r_2^2).$$

The **oblate spheroid** is formed by the rotation of an ellipse about its minor axis. If a and b are the major and minor semi-axes respectively, and ϵ the eccentricity, the surface

$$= 2\pi a^2 + \pi\,\frac{b^2}{\epsilon}\,\log_e \frac{1 + \epsilon}{1 - \epsilon},$$

and volume $= \tfrac{4}{3}\pi a^2 b$.

The prolate spheroid is formed by the rotation of an ellipse about its major axis ($2a$), data as above.

Surface $=2\pi b^2+2\pi \frac{ab}{\epsilon}\sin^{-1}\epsilon$,

volume $=\frac{4}{3}\pi ab^2$.

SIMPSON'S RULE FOR IRREGULAR AREAS

Divide the area into an even number ($2m$) of panels by means of $2m+1$ parallel lines, drawn at constant distance h apart; and denote the lengths of the intercepted segments by $y_0, y_1, \ldots, y_{2m-1}, y_{2m}$. The first and last of these may be zero. The area will then be

$$A=\tfrac{1}{3}h[(y_0+y_{2m})+4(y_1+y_3+\ldots+y_{2m-1})+2(y_2+y_4+\ldots+y_{2m-2})]$$

While the formula is exact in many simple cases, ordinarily the formula provides only an approximation, for which the accuracy increases with an increase in the number of divisions. Simpson's Rule may be applied to finding volumes, if the measures $y_0, y_1, \ldots, y_{2m}$ be interpreted as the areas of parallel plane sections at constant distance h apart.

PRISMOIDAL FORMULA

As a special case where $m=1$, and H, ($=2h$) is the distance between two limiting parallel planes, one has for the volume of a solid figure,

$$V=\tfrac{1}{6}H(S_0+4S_1+S_2).$$

Here S_0 and S_2 are the cross-sectional areas in these limiting planes (lower and upper bases, respectively), and S_1 is the cross section of the mid-section. The formula is exact for the cone, sphere, ellipsoid, and prismoid.

TRIGONOMETRIC FORMULAE

TRIGONOMETRIC FUNCTIONS IN A RIGHT-ANGLED TRIANGLE

If A, B, and C are the vertices (C the right angle), and a, b, and h the sides opposite respectively,

$$\text{sine } A = \sin A = \frac{a}{h}, \qquad \text{cosine } A = \cos A = \frac{b}{h},$$

$$\text{tangent } A = \tan A = \frac{a}{b}, \qquad \text{cotangent } A = \cot A = \text{ctn } A = \frac{b}{a},$$

$$\text{secant } A = \sec A = \frac{h}{b}, \qquad \text{cosecant } A = \csc A = \frac{h}{a}.$$

$$\text{exsecant } A = \text{exsec } A = \sec A - 1$$

$$\text{versine } A = \text{vers } A = 1 - \cos A$$

$$\text{coversine } A = \text{covers } A = 1 - \sin A$$

$$\text{haversine } A = \text{hav } A = \tfrac{1}{2} \text{ vers } A$$

EXPONENTIAL DEFINITIONS OF CIRCULAR FUNCTIONS

$$\sin x = \frac{1}{2i}(e^{ix} - e^{-ix}) \qquad (i^2 = -1)$$

$$\operatorname{cosec} x = \frac{2i}{e^{ix} - e^{-ix}}$$

$$\cos x = \frac{e^{ix} + e^{-ix}}{2}$$

$$\sec x = \frac{2}{e^{ix} + e^{-ix}}$$

$$\tan x = \frac{e^{ix} - e^{-ix}}{ie^{ix} + ie^{-ix}}$$

$$\cot x = \frac{ie^{ix} + ie^{-ix}}{e^{ix} - e^{-ix}}$$

RELATIONS OF THE FUNCTIONS

$$\sin x = \frac{1}{\operatorname{cosec} x}.$$

$$\operatorname{cosec} x = \frac{1}{\sin x}.$$

$$\cos x = \frac{1}{\sec x}.$$

$$\sec x = \frac{1}{\cos x}.$$

$$\tan x = \frac{1}{\cot x} = \frac{\sin x}{\cos x}.$$

$$\sin^2 x + \cos^2 x = 1.$$

$$\cot x = \frac{1}{\tan x} = \frac{\cos x}{\sin x}.$$

$$1 + \tan^2 x = \sec^2 x.$$

$$1 + \cot^2 x = \operatorname{cosec}^2 x.$$

$${}^{*}\sin x = \pm\sqrt{1 - \cos^2 x}.$$

$$\cos x = \pm\sqrt{1 - \sin^2 x}.$$

$$\tan x = \pm\sqrt{\sec^2 x - 1}.$$

$$\sec x = \pm\sqrt{\tan^2 x + 1}.$$

$$\cot x = \pm\sqrt{\operatorname{cosec}^2 x - 1}.$$

$$\operatorname{cosec} x = \pm\sqrt{\cot^2 x + 1}.$$

$$\sin x = \cos(90^\circ - x) = \sin(180^\circ - x).$$

---

* The sign in front of radical depends on quadrant in which x falls.

RELATIONS OF THE FUNCTIONS (Continued)

$\cos x = \sin(90^\circ - x) = -\cos(180^\circ - x).$

$\tan x = \cot(90^\circ - x) = -\tan(180^\circ - x).$

$\cot x = \tan(90^\circ - x) = -\cot(180^\circ - x).$

$$\operatorname{cosec} x = \cot\frac{x}{2} - \cot x.$$

FUNCTIONS OF SUMS OF ANGLES

$\sin(x \pm y) = \sin x \cos y \pm \cos x \sin y.$

$\cos(x \pm y) = \cos x \cos y \mp \sin x \sin y.$

$$\tan(x \pm y) = \frac{\tan x \pm \tan y}{1 \mp \tan x \tan y}.$$

FUNCTIONS OF MULTIPLE ANGLES

$\sin 2x = 2 \sin x \cos x.$

$\cos 2x = \cos^2 x - \sin^2 x = 2\cos^2 x - 1 = 1 - 2\sin^2 x.$

$\sin 3x = 3 \sin x - 4 \sin^3 x.$

$\cos 3x = 4 \cos^3 x - 3 \cos x.$

$\sin 4x = 8 \cos^3 x \sin x - 4 \cos x \sin x.$

$\cos 4x = 8 \cos^4 x - 8 \cos^2 x + 1.$

$\sin 5x = 5 \sin x - 20 \sin^3 x + 16 \sin^5 x.$

$\cos 5x = 16 \cos^5 x - 20 \cos^3 x + 5 \cos x.$

$\sin 6x = 32 \cos^5 x \sin x - 32 \cos^3 x \sin x + 6 \cos x \sin x.$

$\cos 6x = 32 \cos^6 x - 48 \cos^4 x + 18 \cos^2 x - 1.$

$$\tan 2x = \frac{2 \tan x}{1 - \tan^2 x}.$$

$$\cot 2x = \frac{\cot^2 x - 1}{2 \cot x}.$$

$$\tan 3x = \frac{3 \tan x - \tan^3 x}{1 - 3 \tan^2 x}.$$

$${}^*\sin \tfrac{1}{2}x = \pm\sqrt{\frac{1 - \cos x}{2}}.$$

$$\cos \tfrac{1}{2}x = \pm\sqrt{\frac{1 + \cos x}{2}}.$$

$$\tan \tfrac{1}{2}x = \pm\sqrt{\frac{1 - \cos x}{1 + \cos x}} = \frac{1 - \cos x}{\sin x} = \frac{\sin x}{1 + \cos x}.$$

---

* The sign in front of radical depends on quadrant in which x falls.

MISCELLANEOUS RELATIONS

$$\sin x \pm \sin y = 2 \sin \tfrac{1}{2}(x \pm y) \cdot \cos \tfrac{1}{2}(x \mp y).$$
$$\cos x + \cos y = 2 \cos \tfrac{1}{2}(x + y) \cdot \cos \tfrac{1}{2}(x - y).$$
$$\cos x - \cos y = -2 \sin \tfrac{1}{2}(x + y) \cdot \sin \tfrac{1}{2}(x - y).$$
$$\tan x \pm \tan y = \frac{\sin (x \pm y)}{\cos x \cdot \cos y}. \quad \cot x \pm \cot y = \frac{\pm \sin (x \pm y)}{\sin x \cdot \sin y}.$$
$$\frac{1 + \tan x}{1 - \tan x} = \tan (45^\circ + x). \quad \frac{\cot x + 1}{\cot x - 1} = \cot (45^\circ - x)$$
$$\frac{\sin x \pm \sin y}{\cos x + \cos y} = \tan \tfrac{1}{2}(x \pm y).$$
$$\frac{\sin x \pm \sin y}{\cos x - \cos y} = -\cot \tfrac{1}{2}(x \mp y).$$
$$\frac{\sin x + \sin y}{\sin x - \sin y} = \frac{\tan \frac{1}{2}(x + y)}{\tan \frac{1}{2}(x - y)}.$$
$$\sin^2 x - \sin^2 y = \sin (x + y) \cdot \sin (x - y).$$
$$\cos^2 x - \cos^2 y = -\sin (x + y) \sin (x - y).$$
$$\cos^2 x - \sin^2 y = \cos (x + y) \cos (x - y).$$

INVERSE TRIGONOMETRIC FUNCTIONS

The following table lists each of the six inverse trigonometric functions together with the interval of its principal value:

Function	Interval containing principal value	
	x positive or zero	x negative
$y = \sin^{-1} x$ and $\tan^{-1} x$. .	$0 \leqq y \leqq \pi/2$	$-\pi/2 \leqq y < 0$
$y = \cos^{-1} x$ and $\cot^{-1} x$. .	$0 \leqq y \leqq \pi/2$	$\pi/2 < y \leqq \pi$
$y = \sec^{-1} x$ and $\csc^{-1} x$. .	$0 \leqq y \leqq \pi/2$	$-\pi \leqq y \leqq -\pi/2$

Usually the first letter in "arc" or the name of the inverse trigonometric functions is capitalized if the principal value is desired. Thus

$$\text{Arc} \sin \frac{1}{2} = \text{Sin}^{-1} \frac{1}{2} = \frac{\pi}{6},$$

while
$$\text{arc} \sin \frac{1}{2} = \frac{\pi}{6} + 2\pi n \text{ or } \frac{5\pi}{6} + 2\pi n$$

In the calculus both for differentiation or integral formulas, capitalization is not adhered to strictly, but principal values are always understood for inverse trigonometric functions when used unless specifically stated otherwise.

RELATIONS BETWEEN SIDES AND ANGLES OF ANY PLANE TRIANGLE

In a triangle with angles A, B, and C and sides opposite a, b, and c respectively,

$$\frac{a}{\sin A}=\frac{b}{\sin B}=\frac{c}{\sin C}=\text{diameter of the circumscribed circle.}$$

$$a^2=b^2+c^2-2bc\cos A.$$

$$a=b\cos C+c\cos B.$$

$$\cos A=\frac{b^2+c^2-a^2}{2bc}.$$

$$\tan\frac{A-B}{2}=\frac{a-b}{a+b}\cot\frac{C}{2}.$$

$$\sin A=\frac{2}{bc}\sqrt{s(s-a)(s-b)(s-c)},$$

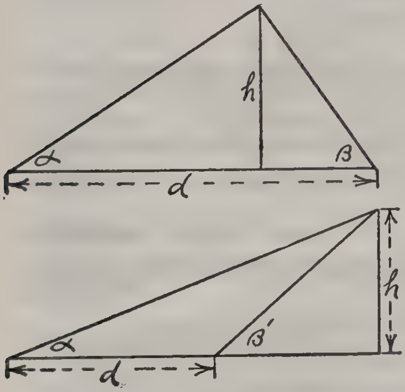
where $s=\frac{1}{2}(a+b+c)$ and $r=\sqrt{\frac{(s-a)(s-b)(s-c)}{s}}$.

$$\sin\frac{A}{2}=\sqrt{\frac{(s-b)(s-c)}{bc}}.$$

$$\cos\frac{A}{2}=\sqrt{\frac{s(s-a)}{bc}}.$$

$$\tan\frac{A}{2}=\sqrt{\frac{(s-b)(s-c)}{s(s-a)}}=\frac{r}{s-a}.$$

$$\frac{a+b}{a-b}=\frac{\sin A+\sin B}{\sin A-\sin B}=\frac{\tan\frac{1}{2}(A+B)}{\tan\frac{1}{2}(A-B)}=\frac{\cot\frac{1}{2}C}{\tan\frac{1}{2}(A-B)}.$$



$$h=d\frac{\sin\alpha\sin\beta}{\sin(\alpha+\beta)}=\frac{d}{\cot\alpha+\cot\beta}$$

Similarly

$$h=d\frac{\sin\alpha\sin\beta'}{\sin(\beta'-\alpha)}=\frac{d}{\cot\alpha-\cot\beta'}$$

FIG. 8.

RELATIONS IN ANY SPHERICAL TRIANGLE

If A, B and C be the three angles and a, b, and c the opposite sides,

$$\frac{\sin A}{\sin a}=\frac{\sin B}{\sin b}=\frac{\sin C}{\sin c}.$$

$$\cos a=\cos b\cos c+\sin b\sin c\cos A=\frac{\cos b\cos(c\pm\theta)}{\cos\theta}.$$

where $\tan\theta=\tan b\cos A.$

$$\cos A=-\cos B\cos C+\sin B\sin C\cos a.$$

$$\sin\tfrac{1}{2}A=\sqrt{\frac{\sin(s-b)\sin(s-c)}{\sin b\sin c}}.$$

where $s=\frac{1}{2}(a+b+c).$

$$\cos\tfrac{1}{2}A=\sqrt{\frac{\sin s\sin(s-a)}{\sin b\sin c}}.$$

$$\tan\tfrac{1}{2}A=\frac{r}{\sin(s-a)}.$$

where $r=\sqrt{\dfrac{\sin(s-a)\sin(s-b)\sin(s-c)}{\sin s}}.$

$$\cos\tfrac{1}{2}a=\sqrt{\frac{\cos(S-B)\cos(S-C)}{\sin B\sin C}}.$$

where $S=\frac{1}{2}(A+B+C).$

$$\sin\tfrac{1}{2}a=\sqrt{-\frac{\cos S\cos(S-A)}{\sin B\sin C}}.$$

$$\tan\tfrac{1}{2}a=R\cos(S-A)$$

where $R=\sqrt{\dfrac{-\cos S}{\cos(S-A)\cos(S-B)\cos(S-C)}}.$

$$\frac{\tan\frac{a+b}{2}}{\tan\frac{c}{2}}=\frac{\cos\frac{A-B}{2}}{\cos\frac{A+B}{2}},\qquad\frac{\tan\frac{A+B}{2}}{\cot\frac{C}{2}}=\frac{\cos\frac{a-b}{2}}{\cos\frac{a+b}{2}}.$$

$$\frac{\tan\frac{a-b}{2}}{\tan\frac{c}{2}}=\frac{\sin\frac{A-B}{2}}{\sin\frac{A+B}{2}},\qquad\frac{\tan\frac{A-B}{2}}{\cot\frac{C}{2}}=\frac{\sin\frac{a-b}{2}}{\sin\frac{a+b}{2}}$$

$$\operatorname{hav} a=\operatorname{hav}(b-c)+\sin b\sin c\operatorname{hav} A$$

$$\operatorname{hav} A=\frac{\sqrt{\operatorname{hav}[a+(b-c)]\operatorname{hav}[a-(b-c)]}}{\sin b\sin c}$$

The distance between two points x_1, y_1, and x_2, y_2,—rectangular coördinates:

$$d = \pm \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$$

For polar coördinates and points r_1, θ_1, and r_2, θ_2:

$$d = \pm \sqrt{r_1^2 + r_2^2 - 2r_1r_2 \cos(\theta_1 - \theta_2)}$$

The area of a triangle whose vertices are x_1, y_1; x_2, y_2, and x_3, y_3:

$$A = \tfrac{1}{2}|x_1y_2 - x_2y_1 + x_2y_3 - x_3y_2 + x_3y_1 - x_1y_3|$$

For polar coördinates and vertices, r_1, θ_1; r_2, θ_2, and r_3, θ_3:

$$A = \tfrac{1}{2}\{r_1r_2 \sin(\theta_2 - \theta_1) + r_2r_3 \sin(\theta_3 - \theta_2) + r_3r_1 \sin(\theta_1 - \theta_3)\}$$

The equation of a straight line where m is the tangent of the angle of inclination and c, the distance of intersection with the Y axis from the origin:

$$y = mx + c$$

If a line of slope m passes through the point x_1, y_1 its equation is:

$$y - y_1 = m(x - x_1)$$

The equation of a line through the points x_1, y_1, and x_2, y_2 is:

$$\frac{y - y_1}{y_2 - y_1} = \frac{x - x_1}{x_2 - x_1}$$

If the intercepts on the X and Y axes are a and b respectively, the equation is:

$$\frac{x}{a} + \frac{y}{b} = 1$$

If the length of the perpendicular from the origin is p and its angle of inclination θ the equation is:

$$x \cos\theta + y \sin\theta = p$$

General equation of the straight line:

$Ax + By + C = 0$, where slope $m = \dfrac{-A}{B}$; x-intercept $a = \dfrac{-C}{A}$; y-intercept $b = \dfrac{-C}{B}$.

The equation of a circle whose center is at a, b, and whose radius is c:

$$(x - a)^2 + (y - b)^2 = c^2$$

If the origin is at the center:

$$x^2 + y^2 = c^2$$

The polar equation of a circle with the origin on the circumference and its center at point c, α:

$$r = 2c \cos(\theta - \alpha).$$

If the origin is not on the circumference, the radius a and the center at a point, l, α, the equation becomes:

$$a^2 = r^2 + l^2 - 2rl \cos(\theta - \alpha)$$

The equation of a parabola with the origin at the vertex, where f is the distance from the focus to the vertex:

$$y^2 = 4fx$$

If p is the semi-latus rectum $(=2f)$ the equation is:

$$y^2 = 2px$$

The polar equation where the pole is at the focus and p the semi-latus rectum is:

$$r = \frac{p}{1 - \cos\theta}$$

If the pole is at the vertex and p as above:

$$r = \frac{2p\cos\theta}{\sin^3\theta}$$

The equation of the ellipse with the origin at the center and semi-axes a and b:

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$$

Polar equation where the pole is at the center:

$$r^2 = \frac{a^2b^2}{a^2\sin^2\theta + b^2\cos^2\theta}$$

The equation of the hyperbola with the origin at the center, semi-axes a and b:

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$$

Polar equation, pole at center:

$$r^2 = \frac{a^2b^2}{a^2\sin^2\theta - b^2\cos^2\theta}$$

TRANSFORMATION OF COORDINATES

Rectangular System

(1) Translation only of axes parallel to themselves.

The coordinates of new origin with respect to old axes: $x = h$, $y = k$. Primed letters designate new coordinates.

$$\begin{aligned} x' &= x - h & \qquad x &= x' + h \\ y' &= y - k & \qquad y &= y' + k \end{aligned}$$

(2) Rotation of axes with fixed origin.

Angle of rotation $= \theta$

$$\begin{aligned} x' &= x \cos\theta + y \sin\theta & \qquad x &= x' \cos\theta - y' \sin\theta \\ y' &= y \cos\theta - x \sin\theta & \qquad y &= y' \cos\theta + x' \sin\theta \end{aligned}$$

(3) Origin translated and axes rotated.

Symbols same as above

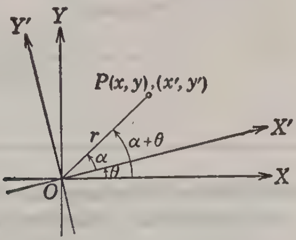
$$\begin{aligned} x' &= (x - h) \cos\theta + (y - k) \sin\theta \\ y' &= (y - k) \cos\theta - (x - h) \sin\theta \\ x &= x' \cos\theta - y' \sin\theta + h \\ y &= y' \cos\theta + x' \sin\theta + k \end{aligned}$$

Relation between Rectangular and Polar Coordinates

$$\begin{aligned} x &= r\cos\theta & \qquad r &= \sqrt{x^2 + y^2} & \qquad \sin\theta &= \frac{y}{\sqrt{x^2 + y^2}} \\ y &= r\sin\theta & \qquad \theta &= \tan^{-1}\frac{y}{x} & \qquad \cos\theta &= \frac{x}{\sqrt{x^2 + y^2}} \end{aligned}$$

Rotation of Polar Axes through Angle θ

$$\begin{aligned} x' &= r\cos\alpha \\ y' &= r\sin\alpha \\ x &= r\cos(\alpha + \theta) \\ y &= r\sin(\alpha + \theta) \end{aligned}$$

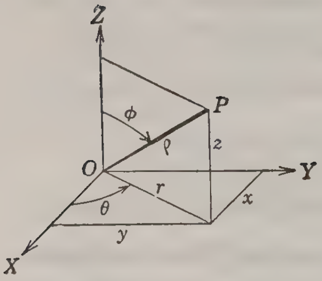


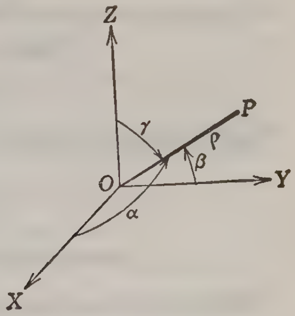
TRANSFORMATION OF COORDINATES (Continued)

SOLID ANALYTICAL GEOMETRY

Space Coordinates

1. Rectangular System x, y, z.
2. Cylindrical System r, θ, z.
3. Spherical System ρ, θ, ϕ.
4. Polar Space System ρ, α, β, γ.





Relations of Coordinates of Systems in Terms of x, y, z

Cylindrical	Spherical	Polar Space
$r = \sqrt{x^2 + y^2}$	$\rho = \sqrt{x^2 + y^2 + z^2}$	$\rho = \sqrt{x^2 + y^2 + z^2}$
$\theta = \tan^{-1}\frac{y}{x}$	$\theta = \tan^{-1}\frac{y}{x}$	$\alpha = \cos^{-1}\left(\frac{x}{\sqrt{x^2 + y^2 + z^2}}\right)$
$z = z$	$\phi = \cos^{-1}\left(\frac{z}{\sqrt{x^2 + y^2 + z^2}}\right)$	$\beta = \cos^{-1}\left(\frac{y}{\sqrt{x^2 + y^2 + z^2}}\right)$
		$\gamma = \cos^{-1}\left(\frac{z}{\sqrt{x^2 + y^2 + z^2}}\right)$

Relations of Rectangular Coordinates (x, y, z) in Terms of Cylindrical, Spherical and Polar Space Coordinates

Cylindrical	Spherical	Polar Space
$x = r \cos\theta$ $y = r \sin\theta$ $z = z$	$x = \rho \sin\phi \cos\theta$ $y = \rho \sin\phi \sin\theta$ $z = \rho \cos\phi$	$x = \rho \cos\alpha$ $y = \rho \cos\beta$ $z = \rho \cos\gamma$

TRANSFORMATION OF COORDINATES (Continued)

TRANSFORMATION OF RECTANGULAR SPACE COORDINATES FOR TRANSLATION WITHOUT ROTATION

Coordinates of new origin are (h, k, l) in terms of the old coordinates. New coordinates are (x', y', z')

$$\begin{aligned} x' &= x - h & x &= x' + h \\ y' &= y - k & y &= y' + k \\ z' &= z - l & z &= z' + l \end{aligned}$$

For rotation only about the origin where λ_1, μ_1, ν_1; λ_2, μ_2, ν_2 and λ_3, μ_3, ν_3 are the direction cosines of the new axes with respect to the old axes. The coordinates of point P are (x, y, z) referred to the original axes and (x', y', z') referred to the new rotated axes.

$$\begin{aligned} x' &= \lambda_1 x + \mu_1 y + \nu_1 z \\ y' &= \lambda_2 x + \mu_2 y + \nu_2 z \\ z' &= \lambda_3 x + \mu_3 y + \nu_3 z \\ x &= \lambda_1 x' + \lambda_2 y' + \lambda_3 z' \\ y &= \mu_1 x' + \mu_2 y' + \mu_3 z' \\ z &= \nu_1 x' + \nu_2 y' + \nu_3 z' \end{aligned}$$

HYPERBOLIC FUNCTIONS

Definitions

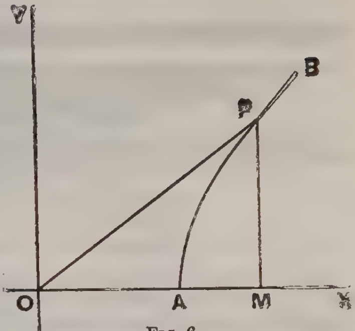


FIG. 6.

An hyperbolic function represents a relation between the coordinates of a given point on the arc of a rectangular hyperbola.

If O is the center, A the vertex, and P any point of the hyperbola APB,

$$\text{OM} = x,\quad \text{MP} = y,\quad \text{OA} = a.$$

The function u may be defined by the following relation,

$$u = \frac{2 \times \text{Area OAP}}{\text{OA}^2}$$

The hyperbolic sine of u = $\sinh u = y/a$.
The hyperbolic cosine of u = $\cosh u = x/a$.

Exponential Definitions of Hyperbolic Functions and Their Power Series

$$\sinh u = \frac{e^u - e^{-u}}{2} = \frac{1}{2}(e^u - e^{-u}) = u + \frac{u^3}{3\,!} + \frac{u^5}{5\,!} + \cdots$$

$$\cosh u = \frac{e^u + e^{-u}}{2} = \frac{1}{2}(e^u + e^{-u}) = 1 + \frac{u^2}{2\,!} + \frac{u^4}{4\,!} + \cdots$$

$$\tanh u = \frac{e^u - e^{-u}}{e^u + e^{-u}} = u - \frac{u^3}{3} + \frac{2u^5}{15} - \frac{17u^7}{315} + \cdots \qquad \left(u^2 < \frac{1}{4}\pi^2\right).$$

$$\sinh^{-1} u = u - \frac{1}{2}\cdot\frac{u^3}{3} + \frac{1\cdot 3}{2\cdot 4}\cdot\frac{u^5}{5} - \frac{1\cdot 3\cdot 5}{2\cdot 4\cdot 6}\cdot\frac{u^7}{7} + \cdots \qquad (u^2 < 1).$$

$$\sinh^{-1} u = \log 2u + \frac{1}{2}\cdot\frac{1}{2u^2} - \frac{1\cdot 3}{2\cdot 4}\cdot\frac{1}{4u^4} + \frac{1\cdot 3\cdot 5}{2\cdot 4\cdot 6}\cdot\frac{1}{6u^6} - \cdots \qquad (u^2 > 1).$$

$$\cosh^{-1} u = \log 2u - \frac{1}{2}\cdot\frac{1}{2u^2} - \frac{1\cdot 3}{2\cdot 4}\cdot\frac{1}{4u^4} - \frac{1\cdot 3\cdot 5}{2\cdot 4\cdot 6}\cdot\frac{1}{6u^6} - \cdots \qquad (u^2 > 1).$$

$$\tanh^{-1} u = u + \frac{u^3}{3} + \frac{u^5}{5} + \frac{u^7}{7} + \cdots \qquad (u^2 < 1).$$

$$\tanh u = \frac{\sinh u}{\cosh u}. \qquad \operatorname{sech} u = \frac{1}{\cosh u}.$$

$$\coth u = \frac{1}{\tanh u}. \qquad \operatorname{csch} u = \frac{1}{\sinh u}.$$

HYPERBOLIC FUNCTIONS (Continued)

Relations of the Functions

$$\sinh x = -\sinh(-x). \qquad \operatorname{sech} x = \operatorname{sech}(-x).$$
$$\cosh x = \cosh(-x). \qquad \operatorname{csch} x = -\operatorname{csch}(-x).$$
$$\tanh x = -\tanh(-x). \qquad \coth x = -\coth(-x).$$

$$\sinh x = \frac{2\tanh\frac{1}{2}x}{1-\tanh^2\frac{1}{2}x} = \frac{\tanh x}{\sqrt{1-\tanh^2 x}}.$$

$$\cosh x = \frac{1+\tanh^2\frac{1}{2}x}{1-\tanh^2\frac{1}{2}x} = \frac{1}{\sqrt{1-\tanh^2 x}}.$$

$$\cosh^2 x - \sinh^2 x = 1.$$

$$\tanh x = \sqrt{1-\operatorname{sech}^2 x}. \qquad \operatorname{sech} x = \sqrt{1-\tanh^2 x}.$$
$$\coth x = \sqrt{\operatorname{csch}^2 x + 1}. \qquad \operatorname{csch} x = \sqrt{\coth^2 x - 1}.$$

$$\sinh(\tfrac{1}{2}x) = \sqrt{\tfrac{1}{2}(\cosh x - 1)}.$$
$$\cosh(\tfrac{1}{2}x) = \sqrt{\tfrac{1}{2}(\cosh x + 1)}.$$
$$\tanh(\tfrac{1}{2}x) = (\cosh x - 1) \div \sinh x = \sinh x \div (\cosh x + 1).$$
$$\sinh(2x) = 2\sinh x\cosh x.$$
$$\cosh(2x) = \cosh^2 x + \sinh^2 x = 2\cosh^2 x - 1 = 1 + 2\sinh^2 x$$
$$\tanh(2x) = 2\tanh x \div (1 + \tanh^2 x).$$
$$\sinh 3x = 3\sinh x + 4\sinh^3 x.$$
$$\cosh 3x = 4\cosh^3 x - 3\cosh x.$$
$$\tanh 3x = (3\tanh x + \tanh^3 x) \div (1 + 3\tanh^2 x).$$
$$\sinh(x \pm y) = \sinh x \cdot \cosh y \pm \cosh x \cdot \sinh y.$$
$$\cosh(x \pm y) = \cosh x \cdot \cosh y \pm \sinh x \cdot \sinh y.$$
$$\tanh(x \pm y) = (\tanh x \pm \tanh y) \div (1 \pm \tanh x \cdot \tanh y).$$
$$\sinh x + \sinh y = 2\sinh\tfrac{1}{2}(x+y) \cdot \cosh\tfrac{1}{2}(x-y).$$
$$\sinh x - \sinh y = 2\cosh\tfrac{1}{2}(x+y) \cdot \sinh\tfrac{1}{2}(x-y).$$
$$\cosh x + \cosh y = 2\cosh\tfrac{1}{2}(x+y) \cdot \cosh\tfrac{1}{2}(x-y).$$
$$\cosh x - \cosh y = 2\sinh\tfrac{1}{2}(x+y) \cdot \sinh\tfrac{1}{2}(x-y).$$

$$\sinh x + \cosh x = \frac{1+\tanh\frac{1}{2}x}{1-\tanh\frac{1}{2}x}$$

$$\tanh x \pm \tanh y = \frac{\sinh(x \pm y)}{\cosh x\cosh y}.$$

$$\coth x \pm \coth y = \pm\frac{\sinh(x \pm y)}{\sinh x\sinh y}.$$

Inverse Functions

$$\sinh^{-1} x = \log(x + \sqrt{x^2+1}) = \int\frac{dx}{\sqrt{x^2+1}} = \cosh^{-1}\sqrt{x^2+1}.$$

$$\cosh^{-1} x = \log\,(x + \sqrt{x^2 - 1}) = \int \frac{dx}{\sqrt{x^2 - 1}} = \sinh^{-1} \sqrt{x^2 - 1}.$$

$$\tanh^{-1} x = \frac{1}{2}\log\,(1 + x) - \frac{1}{2}\log\,(1 - x) = \int \frac{dx}{1 - x^2}.$$

$$\coth^{-1} x = \frac{1}{2}\log\,(1 + x) - \frac{1}{2}\log\,(x - 1) = \int \frac{dx}{1 - x^2}.$$

$$\operatorname{sech}^{-1} x = \log\left(\frac{1}{x} + \sqrt{\frac{1}{x^2} - 1}\right) = -\int \frac{dx}{x\sqrt{1 - x^2}}.$$

$$\operatorname{csch}^{-1} x = \log\left(\frac{1}{x} + \sqrt{\frac{1}{x^2} + 1}\right) = -\int \frac{dx}{x\sqrt{x^2 + 1}}.$$

Relations to Circular Functions

$$\begin{aligned} \sinh x &= -i \sin ix. & \sinh ix &= i \sin x. \\ \cosh x &= \cos ix. & \cosh ix &= \cos x. \\ \tanh x &= -i \tan ix. & \tanh ix &= i \tan x. \end{aligned}$$

If $x = \log \tan\left(\frac{\pi}{4} + \frac{\theta}{2}\right) = \log\,(\sec\theta + \tan\theta)$,

θ = the **gudermannian** of $x = \operatorname{gd} x$.

$$\begin{aligned} \sinh x &= \tan \operatorname{gd} x. & \tanh x &= \sin \operatorname{gd} x. \\ \cosh x &= \sec \operatorname{gd} x. & \tanh \tfrac{1}{2} x &= \tan \tfrac{1}{2} \operatorname{gd} x. \end{aligned}$$

$$\frac{d \operatorname{gd} x}{dx} = \operatorname{sech} x.$$

Integrals involving the hyperbolic functions will be found in the table of integrals.

ELLIPTIC FUNCTIONS

$$u = F(k, \phi) = \int_0^{\phi} \frac{d\Phi}{\sqrt{1 - k^2 \sin^2 \Phi}}, \qquad (k^2 < 1),$$

= elliptic integral of the first kind.

$$u = \int_0^{x} \frac{dx}{\sqrt{(1 - z^2)(1 - k^2 z^2)}}, \quad \text{where } x = \sin \phi.$$

ϕ is called the amplitude of u or am u.
k is called the modulus.

$k' = \sqrt{1 - k^2}$ = the complementary modulus.

$\sin \phi = \operatorname{sn} u = x.$ $\qquad \tan \phi = \operatorname{tn} u = \dfrac{x}{\sqrt{1 - x^2}}.$

$\cos \phi = \operatorname{cn} u = \sqrt{1 - x^2}.$ $\qquad \Delta\phi = \operatorname{dn} u = \sqrt{1 - k^2 x^2}.$
$\operatorname{am} 0 = 0.$ $\qquad \operatorname{sn} 0 = 0.$
$\operatorname{cn} 0 = 1.$ $\qquad \operatorname{dn} 0 = 1.$
$\operatorname{am} (-u) = -\operatorname{am} u.$ $\qquad \operatorname{sn} (-u) = -\operatorname{sn} u.$
$\operatorname{cn} (-u) = \operatorname{cn} u.$ $\qquad \operatorname{dn} (-u) = \operatorname{dn} u.$
$\operatorname{tn} (-u) = -\operatorname{tn} u.$
$\operatorname{sn}^2 u + \operatorname{cn}^2 u = 1.$
$\operatorname{dn}^2 u + k^2 \operatorname{sn}^2 u = 1.$
$\operatorname{dn}^2 u - k^2 \operatorname{cn}^2 u = 1 - k^2 = k'^2.$

$$E(\phi, k) = \int_0^{\phi} \sqrt{1 - k^2 \sin^2 \Phi}\, d\Phi$$

$$= \int_0^{x} \frac{\sqrt{1 - k^2 z^2}}{\sqrt{1 - z^2}}\, dx \qquad \text{where } x = \sin \phi.$$

= the elliptic integral of the second kind.

Complete Elliptic Integrals

$$K = \int_0^{\pi/2} \frac{d\Phi}{\sqrt{1 - k^2 \sin^2 \Phi}} = F\left(k, \frac{\pi}{2}\right)$$

$$E = \int_0^{\pi/2} \sqrt{1 - k^2 \sin^2 \Phi}\, d\Phi = E\left(k, \frac{\pi}{2}\right)$$

ATOMIC WEIGHTS

For the sake of completeness all known elements are included in the list. Several of those more recently discovered are represented only by the unstable isotopes. The value in parenthesis in the atomic weight column is, in each case, the mass number of the most stable isotope.

Name	Symbol	At. No.	International atomic weight		Valence
			1925	1956	
Actinium	Ac	89	....	227	....

* Note irregularity.

THE ELEMENTS

By Harrison Hale

The most striking fact about the elements is their unequal distribution and occurrence. In the earth's crust, including the ocean and the atmosphere, F. W. Clarke reported after careful calculation that oxygen makes up 50% and silicon 25%, the two elements being three-fourths of all matter. Further he concludes that twelve elements form 99% of all this material, leaving only 1% for the other elements. Fully half of the elements are of minor commercial importance at present. No one knows when an element may become of unusual commercial importance. Several theories have been suggested to explain this wide difference in occurrence, but none of these is generally accepted. Of the twelve most common elements only one has an atomic weight of more than 40, iron with 56. The lightness of these common elements is emphasized by the heaviness of the other elements with atomic weights above 200. And yet by no means are all the light elements common.

Besides the weight of the atom it has become increasingly evident that other characteristics are of the greatest importance. F. W. Aston received the Nobel Prize in 1922 for his discovery of isotopes. The discovery of the electron, of the X-ray, and of radioactivity made possible an explanation of isotopes, and the study of atomic energy has given an idea of their very large number. Each element from atomic number 1 to 96 has at least one radioactive isotope. More than 400 of these isotopes are known.

Actinium (Gr. *aktis, aktinos*, beam or ray), Ac; at. wt. 227; at. no. 89. Discovered in 1899 by Andre Debierne and independently by F. Giesel in 1902. Radioactive, decomposing into other elements of smaller atomic weight at certain intervals of time. It is a more basic higher homolog of lanthanum.

Aluminum (L. *alumen*, alum), Al; at. wt. 26.98; at. no. 13; m.p. 659.7°C; b.p. 2057°C; sp. gr. 2.699 (20°C); valence 3. Wöhler is generally accredited with obtaining the metal in 1827, though an impure form was prepared by Oersted two years earlier. The method of obtaining the metal by electrolysis of pure alumina dissolved in cryolite was patented independently by Hall in the United States and Heroult in France, soon after its discovery in 1886. Although aluminum occurs in larger quantities than any other metal, ranking third among all elements, it does not appear free. It is found as the silicate in clays, feldspars, etc., while the commercial ore at present is bauxite, an impure hydrated oxide. Its production from clay is possible. The metal is white and strongly resists the action of the air, becoming covered with a white oxide coating in time; it was selected as the cap for Washington's monument, and is widely used for outside building decoration. It stands second among metals in the scale of malleability, sixth in ductility. The electrical conductivity is about 60% that of copper per area of cross-section, but aluminum is much lighter, giving it use for transmission lines. It is but slightly magnetic and is strongly electro-positive, so that in contact with many other metals it corrodes rapidly. Its many alloys have strength and lightness, finding increasing use. The compounds of greatest importance are its oxide, its sulfate, and its double sulfate with potassium (alum). The oxide, alumina, occurs naturally as ruby, sapphire, corundum and emery, and is very hard, ranking next to the diamond. War's necessity increased greatly the production of aluminum, and this has extended widely its use in time of peace. In 1856 the price was about $90 a pound, thirty years later just before Hall's discovery about $5. Then the price dropped rapidly to 30¢ and has gone as low as 15¢.

****Americium** (the Americas), Am; at. wt. 243; at. no. 95; valence 3, 4, 5, or 6. Observed in fission products in 1945 by Glenn T. Seaborg, R. A. James, L. O. Morgan, and A. Ghiorso working in the Metallurgical Laboratory in Chicago. As a member of the actinide series of elements with its six 5f electrons, Seaborg suggested the name americium by analogy with europium of the lanthanide series with its six 4f electrons.

Antimony (L. *antimonium*), Sb; (L. *stibium*, mark); at. wt. 121.76; at. no. 51; m.p. 630.5°C; b.p. 1380°C; sp. gr. 6.691 (20°C); valence 3 or 5. Recognized in compounds by the ancients; known as a metal at the beginning of the seventeenth century and possibly before that date. Antimony is a metallic element, common, but neither abundant nor widely diffused; sometimes found native, but more frequently as the sulfide, *stibnite* (Sb_2S_3); also as antimonides and sulfantimonides of the heavy metals, and as oxides. It is extracted from the sulfide by roasting to the oxide, which is reduced by salt and scrap iron; from its oxides it is also prepared by reduction with carbon. Antimony is an extremely brittle metal of a flaky, crystalline texture, blue-white color and metallic luster; hardness, 3 to 3.5; not acted on by air at room temperature, but burns brilliantly when heated with formation of white fumes of oxide Sb_2O_3; it is a poor conductor of heat and electricity. The metal is widely used in alloys in a percentage varying from one to twenty. It greatly increases the hardness and mechanical strength of lead Batteries, antifriction alloys, type metal, cable sheathing, and minor products use about half of the metal. Compounds taking up the other half are oxides, sulfide, sodium antimonate, and antimony trichloride. These are used in the manufacture of flame proofing compounds, in paints, ceramic enamels, glass, and pottery. Tartar emetic (hydrated potassium antimonyl tartrate) is used as a medicine.

Argon (Gr. *argon*, inactive), A; at. wt. 39.944; at. no. 18; m.p. −189.2°C; b.p. −185.7°C; density 1.7837 g/l; valence 0 (does not combine with any other element). Its presence in air was suspected by Cavendish in 1785; discovered by Lord Rayleigh and Sir William Ramsay in 1894. The gas is prepared by fractionation of liquid air, the atmosphere containing 0.94% argon. It is 2½ times as soluble in water as nitrogen, having about the same solubility as oxygen; best recognized by the characteristic lines in the red end of the spectrum. It is used in electric light bulbs and in fluorescent tubes at a pressure of about 3 mm.

** For further description see following section "Transuranium Elements."

Arsenic (L. *arsenicum*, Gr. *arsenikon*, yellow orpiment—identified with *arsenikos*, male, from the belief that metals were of different sexes—Arab. *az-zernikh*, the orpiment from Persian *zerni-zar*. gold-), As; at. wt. 74.91; at. no. 33; m.p. $814^{36\text{ atm.}}$; b.p. 615°C; sp. gr. 5.73; valence 3 or 5. The amorphous form of arsenic has a sp. gr. of 3.70. It is believed that Albertus Magnus obtained the element in 1250. In 1649 Schroeder published two methods of preparing it. Found native, in sulfides, *realgar* and *orpiment*, as arsenides and sulfarsenides of heavy metals and as oxide, and arsenate. *Mispickel* or arsenopyrite ($FeSAs$) is the most common mineral, from which on heating the arsenic sublimes leaving ferrous sulfide. The element is a steel gray, very brittle, crystalline, semi-metallic solid, which sublimes on heating, being deposited partly as crystals and partly as a black, amorphous solid; it tarnishes in air and when heated is rapidly oxidized to arsenous oxide (As_2O_3) with the odor of garlic. Though the free element is not considered poisonous, many of its compounds are extremely so, being used as insecticides. Arsenic is also used in bronzing, pyrotechny, and for hardening and improving the sphericity of shot. The most important compounds are white arsenic (As_2O_3), the sulfide, Paris green $3Cu(AsO_2)_2 \cdot Cu(C_2H_3O_2)_2$, calcium arsenate and lead arsenate, the last three being used in agricultural poisons. Marsh's test makes use of the formation and ready decomposition of arsine (AsH_3). Important war gases as Adamsite and Lewisite, are compounds of arsenic.

Astatine (Gr. astatos, unstable) At; at. wt. 210; at no. 85; valence probably 1, 3, 5, or 7. Synthesized in 1940 by D. R. Corson, K. R MacKenzie, and E. Segré at the University of California by bombarding bismuth with alpha-particles. It is the only halogen without stable isotope.

Barium (Gr. *barys*, heavy), Ba; at. wt 137.36; at. no. 56; m.p. 850°C; b.p. 1140°C; sp. gr. 3.5 (20°C); valence 2. Baryta was distinguished from lime by Scheele in 1774; the element was discovered by Sir Humphry Davy in 1808. It is found only in combination with other elements chiefly in *barite* or *heavy spar* (sulfate) and *witherite* (carbonate) and is prepared by electrolysis of the chloride Barium is a metallic element, soft and silvery white like lead; it belongs to the alkaline earth group, resembling calcium chemically The most important compounds are the peroxide (BaO_2), chloride, sulfate, carbonate, nitrate and chlorate. The sulfate, as permanent white or *blanc fixé*, is used in paint, the carbonate as a rat poison, while the nitrate and chlorate give green colors in pyrotechny. The sulfide phosphoresces after exposure to the light. The compounds are not expensive and the metal is not in great demand.

****Berkelium** (Berkeley, home of the University of California), Bk, at. wt. 245; at. no. 97; valence 3 or 4. Discovered early in 1950 by Glenn T. Seaborg, Stanley G. Thompson, and Albert Ghiorso, University of California scientists, working under the

---

** For further description see following section "Transuranium Elements."

sponsorship of the U. S. Atomic Energy Commission. Produced by irradiation of americium-241 with helium ions in the Berkeley 60 inch cyclotron. Decays with a 4.8 hour half-life by electron capture. An actinide homologue of the element terbium (No. 65) with similar properties; as its earlier homologue it is named for the town of discovery.

Beryllium (L. fr. *beryl;* also called *Glucinum,* Gr. *glykys,* sweet), Be; at. wt. 9.013; at. no. 4; m.p. 1278 ± 5°C; b.p. 2970^{760}°C (5 mm.); sp. gr. 1.8 (20°C); valence 2. Discovered as the oxide by Vauquelin in beryl and in emerald in 1798; the metal was isolated in 1828 by Wöhler and by Bussy independently. Beryllium aluminum silicates are the chief sources of the metal today. It is prepared by electrolysis of the double fluoride, K_2BeF_4. Hard enough to scratch glass, the metal resembles magnesium in appearance and chemical properties. Its soluble compounds are sweet. Its alloys are strong, light and resistant to corrosion. The metal is widely found, but in only small quantities of ore. The use in light alloys is increasing with the decrease in price of the metal. Addition of small amounts brings to the alloy much higher fatigue endurance.

Bismuth (Ger. *Weisse Masse,* white mass; later *Wismuth*). Bi; at. wt. 209.00; at. no. 83; m.p. 271.3°C; b.p. 1560 ± 5^{760}°C; sp. gr, 9.747; valence 3 or 5. In early times bismuth was confused with tin and lead. Claude Geoffroy showed it to be distinct from lead in 1753. It is a white, crystalline, brittle metal with a pinkish tinge. It occurs native, but the common ore is the sulfide, *bismuthinite;* from this it is extracted by melting out the free metal, the oxides and sulfides being decomposed by the addition of carbon and iron. It is also recovered as a by-product in lead smelting. Bismuth is a poor conductor of electricity, is very diamagnetic, solidifies with expansion, heated in air it burns with a blue flame forming yellow fumes of the oxide. It forms many alloys with metals, which are often used in fire extinguishers for their property of low melting (fusible metals) and because of their expansion on cooling, making them particularly suited for sharp castings of objects subject to damage by high temperatures. Its soluble salts are characterized by forming insoluble basic salts on the addition of water—a property sometimes used in detection. The important compounds are the trioxides and the subnitrates of medicinal use, (*pearl white, pearl powder, blanc de fard* and *blanc d'Espagne*).

Boron (Ar. *būraq,* Pers. *būrah*), B; at. wt. 10.82; at. no. 5; m.p. 2300°C; b.p. sublimes 2550°C; sp. gr. of crystals 3.33^{20}, of amorphous variety 2.34; valence 3. Discovered in 1808 by Sir Humphry Davy and by Gay-Lussac and Thenard. The element is not found free in nature, but occurs as orthoboric acid usually in certain volcanic spring waters and as borates in *borax* and *colemanite.* Boron is obtained by heating the trioxide with magnesium powder, and has little or no commercial value The most important compounds are boric, or boracic, acid widely used as a mild antiseptic, and borax ($Na_2B_4O_7.10H_2O$), which serves as a cleansing flux in welding and as a water softener in washing powders. Boron compounds are used in production of enamels and glasses for covering steel in refrigerators, washing machines, and like products.

Bromine (Gr. *bromos*, stench), Br; at. wt. 79.916; at. no. 35; m.p. −7.2°C; b.p. 58.78°C; density of gas 7.59 g/l, liquid 3.12 (20°C); valence 1, 3, 5, or 7. Discovered by Balard in 1826, but not prepared in quantity until 1860. A member of the halogen group of elements, it is obtained from natural brines from wells in Michigan and West Virginia and from sea water by displacement with chlorine; electrolysis might be used. Bromine is the only liquid non-metallic element. It is a heavy, mobile, reddish-brown liquid, volatilizing readily at room temperature to a red vapor with a strong disagreeable odor, resembling chlorine, and having a very irritating effect on the eyes and throat; it is readily soluble in water or carbon disulfide, forming a red solution; it is less active than chlorine but more so than iodine; it unites readily with many elements and has a bleaching action; when spilled on the skin it produces painful sores. It is chiefly employed for the preparation of its compounds, which are useful in photography, medicine, coal tar derivatives, and as ethylene bromide in anti-knock gasoline. Organic compounds are important.

Cadmium (Gr. *kadmia*, earth), Cd; at. wt. 112.41; at. no. 48; m.p. 320.9°C; b.p. 767°C; sp. gr. 8.65 (20°C); valence 2 Discovered by Stromeyer in 1817 from an impurity in zinc carbonate Cadmium occurs in small quantities associated with zinc It comes off before zinc in the preparation of the metal, condensing as the brown oxide, which is then reduced with carbon. It tarnishes in air and burns when heated, forming the oxide. It is a soft, bluish-white metal, used in standard cells for the accurate determination of E.M.F. The use of the metal industrially has increased greatly; it is a component of one of the lowest melting alloys; it is extensively used in bearing alloys with low coefficients of friction and great resistance to fatigue; it is used in electroplating. Cadmium barriers to control atomic fission greatly increased U. S. production. It forms a number of salts of which the sulfate is the most common; the sulfide is used as a yellow pigment.

Calcium (L. *calx*, lime), Ca; at. wt. 40.08; at. no. 20; m.p. 842–8°C; b.p. 1240°C; sp. gr. 1.55 (20°C); valence 2. Though lime was prepared by the Romans in the first century under the name calx, not until 1808 was the metal discovered by Davy and by Berzelius and Pontin independently by preparation of an amalgam electrolytically and removal of the mercury by distillation. Calcium is a metallic element, fifth in abundance in the earth's crust, of which it forms more than three per cent; an essential constituent of leaves, bones, teeth and shells. Never found in nature uncombined, it occurs abundantly as *limestone* ($CaCO_3$), *gypsum* ($CaSO_4.2H_2O$) and fluorite (CaF_2); *apatite* is the fluophosphate or chlorophosphate of calcium. It is prepared by electrolysis of the fused chloride; chemically it is one of the alkaline earth elements; it readily forms a white coating of oxide in the air, reacts with water, burns with a yellow red flame to the oxide. Its natural and prepared compounds are widely used. Quick lime (CaO) made by heating limestone and changed into slaked lime by the careful addition of water is the great cheap base of chemical industry with countless uses. Mixed with sand it hardens as mortar and plaster by taking up carbon dioxide from the air. Calcium from limestone is an important element in Portland cement. The solubility of the carbonate in water containing carbon dioxide causes the formation of caves with stalactites and stalagmites and hardness in water. Other important compounds are the carbide (CaC_2), chloride ($CaCl_2$), cyanamide ($CaCN_2$), hypochlorite ($Ca(OCl)_2$), nitrate $Ca(NO_3)_2$, and sulfide (CaS).

****Californium** (State of California) Cf; at. wt. 248; at. no. 98. Discovered in 1950 by Glenn T. Seaborg, Stanley G. Thompson, Albert Ghiorso, and Kenneth Street, Jr., University of California scientists, working under the sponsorship of the U. S. Atomic Energy Commission. Produced by bombarding a few millionths of a gram of curium-242 with 35 m.e.v. alpha particles in the 60 inch cyclotron at Berkeley. It is an alpha emitter with a half-life of only 45 minutes. An actinide homologue of the element dysprosium (No. 66) with similar properties.

Carbon (L. *carbo*, charcoal), C; at. wt. 12.011; at. no. 6; m.p. 3550°C, sublimes above 3500°C; b.p. 4200°C; sp. gr. amorphous 1.88, graphite 2.25, diamond 3.51; valence 2, 3 or 4. Carbon, an element of prehistoric discovery and characteristic of organic matter, is very widely distributed in nature, occurring free as diamond and graphite. In combination it is found as carbon dioxide in the atmosphere and dissolved in all natural waters, as great rock masses composed of carbonates of calcium, magnesium and iron, as hydrocarbons in supplies of petroleum and natural gas. Coal consists chiefly of carbon compounds. It appears in three allotropic forms, diamond, graphite and amorphous, all solids, insoluble in any common solvent but dissolving in melted metals from which it crystallizes on cooling in the form of graphite; when the cooling takes place under pressure some of the carbon is obtained as diamond. Carbon is unique in forming an almost infinite number of compounds, often linking carbon atom to carbon atom, there being at present half a million known compounds. Some of the most important compounds are carbon dioxide, carbon monoxide, carbon disulfide, chloroform ($CHCl_3$), carbon tetrachloride (CCl_4), methane (CH_4), ethylene (C_2H_4), acetylene (C_2H_2), benzene (C_6H_6), ethyl alcohol (C_2H_5OH), acetic acid (CH_3COOH) and countless derivatives.

Cerium (named for the planetoid *Ceres*, which was discovered in 1801 only two years before the element), Ce; at. wt. 140.13; at. no. 58; m.p. 804°C; b.p. 1400°C; sp. gr. 3.92 (20°C); valence 3 or 4. Discovered in 1803 by Klaproth and by Berzelius and Hisinger; metal prepared by Hillebrand and Norton in 1875. Cerium is the most abundant of the metals from the so-called

** For further description see following section "Transuranium Elements."

rare earths; it is found in a number of minerals including *orthite*, *cerite* and *samarskite* of North Carolina. The metal exists in three, and possibly four, allotropic states. Prepared by the electrolysis of the chloride it is a steel-gray lustrous metal; used as a pyrophoric alloy with iron, it gives off showers of sparks when struck. As the oxide it is an important constituent of incandescent gas mantles; as ceric sulfate it finds extensive use as a volumetric oxidizing agent in quantitative analysis.

Cesium (L. *caesius*, sky blue), Cs; at. wt. 132.91; at. no. 55; m.p. 28.5°C; b.p 670°C; sp. gr. 1.873 (20°C); valence 1. The first metal discovered by Bunsen and Kirchhoff with the spectroscope. This was in 1860, the source being a mineral water from Dürkheim. Cesium is an alkali metal occurring in *lepidolite*, *pollucite* (a hydrated silicate of aluminum and cesium) and in the water from certain mineral springs; it is isolated by electrolysis of the fused cyanide. The metal is characterized by a spectrum containing two bright lines in the blue along with several others in the red, yellow and green. Because of its great affinity for oxygen the metal is used as a "getter" in radio tubes. It is also used in photo-electric cells, as well as for a catalyst in the hydrogenation of certain organic compounds. Its chief compounds are the chloride and the nitrate.

Chlorine (Gr. *chloros*, greenish-yellow), Cl; at. wt. 35.457; at. no. 17; m.p. −103 ± 5°C; b.p. −34.6°C; density 3.214 g/l; sp. gr. 1.56 (−33.6°C); valence 1, 3, 5 or 7. Discovered in 1774 by Scheele, who thought it contained oxygen; named in 1810 by Davy, who insisted it was an element. In nature it is found in the combined state only, chiefly with sodium as common salt (NaCl), *carnallite* ($KMgCl_3.6H_2O$), and *sylvite* (KCl). A member of the halogen (salt forming) group of elements it is obtained from chlorides by the action of oxidizing agents and more often by electrolysis; it is a greenish-yellow gas, with an irritating and suffocating odor, attacking the respiratory tract; combines directly with nearly all elements. At 10°C one volume of water dissolves 3.10 volumes of chlorine, at 30° only 1.77 volumes. Being a heavy gas, it was first used as a war gas by the Germans in 1915; most war gases contain chlorine. Berthollet suggested its use for bleaching, a most important reagent for vegetable fibers to-day. Around the globe it is used as a germicide in drinking water; further use is in the manufacture of bleaching powder, hypochlorites and chlorates, chloroform, carbon tetrachloride and in the extraction of bromine. Organic chemistry demands much both as an oxidizing agent and in substitution, since it often brings desired properties in an organic compound when substituted for hydrogen, as in one form of synthetic rubber.

Chromium (Gr. *chroma*, color), Cr; at. wt. 52.01; at. no. 24; m.p. 1890°C; b.p. 2480°C; sp. gr. 7.1 (20°C); valence, 2, 3, or 6. Discovered in 1797 by Vauquelin, who prepared the metal the next year. Chromium is a metallic element, resembling iron, occurring chiefly in chrome iron ore ($FeO \cdot Cr_2O_3$), prepared by the reduction of the oxide with aluminum; it is a very infusible, hard gray metal, used to harden steel, to manufacture stainless steel and in many very useful alloys. Much is used in plating, giving a hard, beautiful surface. It finds wide use as a catalyst. All compounds of chromium are colored; the most important are the chromates of sodium and potassium (K_2CrO_4) and the dichromates ($K_2Cr_2O_7$) and the potassium and ammonium chrome alums $KCr(SO_4)_2.12H_2O$. The dichromates are used as oxidizing agents in quantitative analysis, also in tanning leather. Other compounds are of industrial value; lead chromate is chrome yellow, a valued pigment.

Cobalt (*kobold*, from the German, goblin or evil spirit), Co; at. wt. 58.94; at. no. 27; m.p. 1495°C; b.p. 2900°C; sp. gr. 8.9 (20°C); valence 2 or 3. Discovered by Brandt in 1735. Cobalt is a metal occurring in ores sparingly distributed, usually sulfide or arsenide. It is prepared by reducing the oxide with aluminum; it is brittle, hard, very magnetic, and of a gray color with a reddish tinge. Its alloys are important. Stellite, or stellite type, containing cobalt, chromium, and tungsten, are used for high speed, heavy duty, high temperature cutting, and for dies. It occurs also in magnet steels and stainless steels, and in alloys used in jet-propulsion gas turbine and tubo-superchargers. The metal is used in electroplating because of its appearance, hardness, and resistance. The salts have been used for centuries for the production of brilliant and permanent blue colors in porcelain, glass, pottery, tiles and enamels, being the principal ingredient in *Sevres blue* and *Thenard's blue*. As little as 0.1% of the metal gives an intense blue color. A solution of the chloride ($CoCl_2.6H_2O$) is used as sympathetic ink, the solution being pink and practically colorless when spread on paper, turns blue on heating which removes the water of crystallization. The cobalt ammines are of interest; the oxide and the nitrate are important.

Columbium (see Niobium).

Copper (L. *cuprum*, from the island of Cyprus), Cu; at. wt. 63.54; at. no. 29; m.p. 1083°C; b.p. 2336°C; sp. gr. 8.93–8.95; valence 1 or 2. The discovery of copper dates from prehistoric times; it is said to have been mined for more than 5000 years. Copper is a metallic element, reddish colored, bright, metallic luster, malleable, ductile, a good conductor of heat and electricity (second only to silver in electrical conductivity). It occurs native and in many minerals; the most important of these compounds are sulfides, oxides and carbonates. From these it is obtained by smelting, leaching or electrolysis. Its alloys, brass and bronze, long used are still most important; all American coins are copper alloys; monel and gun metals also contain copper. The most important compounds are the oxide and the sulfate, blue vitriol; the latter has wide use as an agricultural poison and as an algicide in water purification. Copper compounds are widely used in analytical chemistry, as Fehling's solution in tests for sugar.

****Curium** (Pierre and Marie Curie), Cm; at. wt. 245; at. no. 96; chief valence 3. Observed in fission products in 1944 by

---

** For further description see following section "Transuranium Elements."

Glenn T. Seaborg, R. A. James, L. O. Morgan, and A. Ghiorso working in the Metallurgical Laboratory in Chicago. As a member of the actinide series of elements with its seven 5f electrons, Seaborg suggested for it the name curium, honoring the historical leading investigators in the field of radioactivity. This is by analogy with gadolinium, containing seven 4f electrons, which honors Gadolin, the great Finnish investigator of the rare earths.

Deuterium, an isotope of hydrogen—see Hydrogen.

Dysprosium (Gr. *dysprositos*, hard to get at), Dy; at. wt. 162.51; at. no. 66; m.p. . . . . . ; b.p. . . . . ; sp. gr. . . . . ; valence 3. Discovered in 1886 by Lecoq de Boisbaudran. The so-called rare earths may be divided into two groups, the cerium and the yttrium. Dysprosium is in the latter group, a member of the erbium family, closely related to holmium. It is best separated from similar elements by fractional crystallization of the bromates. It occurs in the minerals usually found in granite or in pegmatite veins, such as *xenotime*, *fergusonite*, *gadolinite*, *euxonite*, *polycrase* and *blomstrandine*. The free element has never been isolated; its salts are highly colored.

***Erbium** (Ytterby, a town in Sweden), Er; at. wt. 167.27; at. no. 68; m.p. . . . . . ; b.p. . . . . . . ; sp. gr. 4.77 (?); valence 3. Discovered in 1843 by Mosander. Erbium is in the yttrium group of rare earth metals with atomic numbers of 64 to 71 in addition to yttrium, 39. In order of increasing basicity are included thulium, erbium, holmium and dysprosium, with decreasing atomic weights. Erbium occurs in the minerals mentioned under dysprosium above. It forms an oxide Er_2O_3 and highly colored salts.

Europium (Europe), Eu; at. wt. 152.0; at. no. 63; m.p. 1150 ± 50; bp. . . . . . ; sp. gr. . . . . . . ; valence 2 or 3. Discovered in 1896 by Demarcay. Europium is in the cerium group with atomic numbers from 57 to 63 and related in order of discovery. It is very sparsely distributed and of slight importance at present. Salts of the type EuX_3 and EuX_2, where X is a univalent atom or radical, are known.

***Fluorine** (L. *fluo*, flow), F; at. wt. 19.00; at. no. 9; m.p. −223°C; b.p. −188°C; density 1.69 g/l (15°C); sp. gr. of liquid 1.11 (−187°C); valence 1. Discovered by Scheele in 1771, but not isolated until 1886, by Moissan. It occurs chiefly in *fluor spar* (CaF_2) and *cryolite* (Na_3AlF_6), but seems rather widely distributed. Fluorine, a member of the halogen family of elements, is obtained by electrolyzing a solution of potassium hydrogen fluoride in anhydrous hydrogen fluoride in a vessel of metal or transparent fluorspar. It is a pale yellow gas, uniting directly with silicon, carbon, hydrogen and nearly all other elements in the dark; decomposes almost all compounds to form fluorides. The most important compounds are hydrogen fluoride, which is used in etching glass, and calcium fluoride. Freon-12, used in air conditioning, is difluorodichloro methane. Both the element and hydrofluoric acid are dangerous poisons.

* See new elements Einsteinium and Fermium at end of table.

The presence of fluorides in drinking water to the extent of approximately two parts per million, may cause mottled enamel in teeth, when used by children acquiring permanent teeth. Organic compounds of fluorine are now receiving attention.

Francium (France), Fr; at. wt. 223; at. no. 87; valence 1. Discovered in 1939 by Mlle. Marguerite Perey of the Curie Institute, Paris. It is a natural isotope, occurring as the result of an alpha disintegration of actinium. It has the properties of an alkali metal, and the highest equivalent weight of any element.

Gadolinium (*gadolinite*, name for Gadolin, a chemist of Finland), Gd; at. wt. 157.26; at. no. 64; m.p. . . . ; b.p. . . . . ; sp. gr. . . . . . ; valence 3. Separated by Marignac in 1880 and by Lecoq de Boisbaudran in 1886. In order of discovery gadolinium belongs in the yttrium group, being a member of the terbium family. It is named for the mineral from which the earth was obtained. The free element has never been isolated; the element forms oxides of the type R_2O_3, and its salts are usually more soluble than the corresponding terbium salts; its compounds are more plentiful than those of terbium or of europium. These elements decrease in order of basicity, Eu, Gd, Tb.

Gallium (L. *Gallia*, France), Ga; at. wt. 69.72; at. no. 31; m.p. 29.78°C; b.p. 1983°C; sp. gr. 5.91 (20°C); valence 2 or 3. Discovered spectroscopically by Lecoq de Boisbaudran in 1875, who in the same year obtained the free metal by electrolysis of a solution of the hydroxide in potassium hydroxide. A very rare metal, whose salts resemble those of aluminum; found in traces in many zinc blendes and nearly always in bauxite. Gallium was discovered in zinc blende from a mine in Hautes-Pyrenees; had been predicted and described as eka-aluminum by Mendeleeff. Besides mercury, cesium and rubidium, gallium is the only metal which can be liquid at near room temperatures; this makes possible its use in high temperature thermometers; the solid is hard and grayish-white. The metal forms two sets of oxides and salts in which it has a valence of two or of three.

Germanium (L. *Germania*, Germany), Ge; at. wt. 72.60; at. no. 32; m.p. 958.5°C; b.p. volatilizes at 2700°C; sp. gr. 5.36 (20°C); valence 4. Discovered by Winkler in 1886; had been predicted and described as eka-silicon by Mendeleeff. The metal is prepared by reducing the oxide with carbon or with hydrogen. The oxide was first obtained from *argyrodite*, a sulfide of germanium and silver; in 1916 the mineral, *germanite*, containing 8% of germanium was discovered. Obtained from residues of certain American zinc ores, germanium is separated from other metals by fractional distillation of its volatile tetrachloride. Being in the silicon group, the metal lies between silicon and tin in physical and chemical properties; it is a gray-white, brittle, crystalline metal, retaining its luster in air at room temperatures. The most important compounds are the oxide GeO_2, and the halides, as $GeCl_4$, which is volatile. Used to make transitors in large numbers.

Gold (Sanskrit *Jval;* Anglo-Saxon *gold*), Au (L. *aurum*, shining dawn); at. wt. 197.0; at. no. 79; m.p. 1063°C; b.p. 2600°C; sp. gr. 19.32 (17.5°C); valence 1 or 3. Known and highly valued from earliest times. Gold is found in nature as the free metal and in tellurides; very widely distributed but almost always associated with quartz or pyrite; occurs in veins and in alluvial deposits. The metal is obtained from its ores by cyanidation, amalgamation and smelting. Refining is frequently done by electrolysis. It has been estimated that all the gold in the world could be placed in a single cube, forty feet on the side. As with most metals, recent production has greatly increased. Gold is a metallic element, having a yellow color when in mass, but when finely divided it may be black, ruby or purple; colloidal gold has been used to color ruby cathedral glass windows. It is the most malleable and ductile, and also one of the softest of the metals; it is a good conductor of heat and electricity and is not affected by air and most reagents. Its chief use is in coinage and jewelry, when it is alloyed with other metals, pure gold being expressed as 24 carat. When used as a standard of value by the United States, one Troy ounce was worth $20.67 plus; since 1934 this value has been fixed by law and the President's order at $35.00 per ounce. The commonest compounds are auric chloride ($AuCl_3$) and chlorauric acid ($HAuCl_4$), the latter being used in photography for toning the silver image. A mixture of one part of nitric acid with three of hydrochloric acid is called *aqua regia*, because it dissolves Gold, the King of Metals.

Hafnium (*Hafnia*, Copenhagen), Hf; at. wt. 178.58; at. no. 72; m.p. 1700°C; b.p. above 3200°C; sp gr. 13.3; valence 4. Discovered in 1923 by D Coster and G von Hevesey in a *zircon* from Norway by means of Röntgen spectroscopic analysis. On the basis of the Bohr theory the new element was expected to be associated with zirconium. On treatment of the mineral with potassium bifluoride and separation K_2ZrF_6, the mother liquors became richer in the new element. Apparently all zirconium minerals contain hafnium. It has been separated from zirconia by repeated recrystallization of the double ammonium or potassium fluorides. Metallic hafnium was prepared by passing the vapor of the tetraiodide over a heated tungsten filament; this was done by van Arkel and deBoer; it has the same crystalline structure as zirconium. Hafnium also resembles zirconium in chemical properties. There is an oxide (HfO_2), a white powder, with corresponding hydroxide and salts.

Helium (Gr. *helios*, the sun), He; at. wt. 4.003; at. no. 2; m.p. below −272.2°C (26 atm.); b.p. −268.9°C; density 0.177 g/l; valence 0. Evidence of the existence of helium was first obtained by Janssen during the eclipse of 1868, when he detected a new line in the solar spectrum; Lockyer and Frankland suggested the name for the new element; in 1895 Ramsay isolated helium from *uraninite*. The small amount of helium in the atmosphere does not seem to vary with the altitude up to 25 kilometers (about 15 miles). Helium is a gas, inert chemically, obtained by compression and fractionation of the gas from certain wells and from many radioactive minerals. During World War II the greatly increased production exceeded consumption demand. Onnes has cooled the element to the lowest temperature ever obtained, −272.918°C, and expressed the opinion that helium may remain a liquid even at absolute zero under normal pressure. In 1926 Keesom solidified it under a pressure of 26 atmospheres. Approximately twice as heavy as hydrogen it is used for inflating balloons because it will not burn. A mixture of 80% helium and 20% oxygen is used as an artificial atmosphere for divers and others working under pressure; since helium is less soluble in the blood than nitrogen it does not produce the "bends."

Holmium (L. *Holmia*, for Stockholm), Ho; at. wt. 164.94; at. no. 67; m.p. . . . . . ; b.p. . . . . ; sp. gr. . . . . . ; valence 3. Discovered by Cleve while working on erbia earth in 1879; pure holmia earth was isolated by Homberg in 1911. Holmium is in the yttrium group of rare earth metals in order of discovery; it is a member of the erbium family, which includes thulium, erbium, holmium, dysprosium in the order of increasing basicity. It occurs in gadolinite and similar minerals. The element has not been isolated, but the oxide (Ho_2O_3), pale yellow in color, dissolving in certain acids to produce yellow or orange salts, has been prepared.

Hydrogen (Gr. *hydro*, water, and *genes*, forming), H; at. wt. 1.0080; at. no 1; m.p. −259.14°C; b.p. −252.8°C; density 0.08988 g/l; sp. gr. liquid 0.070 (−252°C); valence 1. First recognized as a distinct substance by Cavendish in 1766; named by Lavoisier Hydrogen occurs chiefly in combination with oxygen as water; also in acids, bases and alcohols as well as in carbohydrates, in petroleum and other hydrocarbons. It is usually a constituent of organic compounds, especially those used as fuels and as food. It is the lightest of all gases, insoluble in water, uniting with many elements to form compounds; it is used as a reducing agent, as a means of obtaining high temperature flames, in atomic hydrogen welding and for inflating balloons. Great quantities are required commercially for the fixation of nitrogen from the air in the Haber ammonia process and for the hydrogenation of fats and oils. It is prepared by action of steam on heated carbon, by decomposition of certain hydrocarbons with heat, by the electrolysis of water, or by the displacement from acids by certain metals. In 1932 Urey announced the preparation of the isotope with an atomic weight of 2, commonly called deuterium; tritium with an atomic weight of 3 was discovered two years later. One part of deuterium is found to about 5000 ordinary hydrogen atoms. Tritium occurs in much smaller proportion, the ratio being only one to 10^{17} atoms of ordinary hydrogen; but tritium is readily produced in the atomic energy pile.

Indium (from its indigo blue spectrum), In; at. wt. 114.82; at. no. 49; m.p. 156.4°C; b.p. 2000 ± 10°C; sp. gr. 7.28 (20°C); valence 1 or 3. Discovered in 1863 by the use of the spectroscope by Reich and Richter, who later isolated the metal. Indium is a rare metallic element, occurring usually in zinc blendes, sometimes with pyrites and siderite. The metal is obtained by electrolysis from baths of complex cyanide, chloride and sulfate. It belongs to the aluminum group in properties, being a very soft, silvery metal, not acted on by water or air, burning to the oxide (In_2O_3). Electroplates of indium increase the resistance of certain bearing alloys to organic acid corrosion. The metal finds use in alloys for jewelry and in dental alloys.

Iodine (Gr. *iodes*, violet), I; at. wt. 126.91; at. no. 53; m.p. 113.5°C; b.p. 184.35°; density of the gas 11.27 g/l; sp. gr. solid 4.93 (20°C); valence 1, 3, 5, or 7. Discovered by Courtois in 1811. Iodine, a halogen, occurs sparingly in the form of iodides in sea water from which it is assimilated by seaweeds, in Chile saltpeter, in brines from old sea deposits and in caliche (as sodium iodate); from iodides it is obtained on treatment with sulfuric acid and some oxidizing agent (MnO_2) and from the iodates by heating with sodium bisulfite. A process patented in the United States in 1932 and 1933, using finely divided silver on brines from salt wells, so increased production that the price was reduced to about one-third. Iodine is a grayish-black lustrous solid, volatilizing at ordinary temperatures into a blue-violet gas with an irritating odor; it forms compounds with many elements, but is less active than the other halogens, which displace it from iodides. It dissolves slightly in water, readily in chloroform, carbon tetrachloride or carbon disulfide to beautiful purple solutions. Iodine compounds are important in organic chemistry. The most common compounds are the iodides of sodium and potassium (KI) and the iodates (KIO_3). Lack of iodine is the cause of goiter. The iodide and thyroxin, which contains iodine, are used internally in medicine, and a solution of iodine in alcohol for external wounds. Potassium iodide finds some use in photography. The deep blue color with starch solution is characteristic of the free element.

Iridium (L. *iris*, rainbow), Ir; at. wt. 192.2; at. no. 77; m.p. 2454°C; b.p. above 4800°C; sp. gr. 22.42 (17°C); valence 3 or 4. Discovered in 1803 by Tennant in the residue left when crude platinum is dissolved by aqua regia. The name shows the colors of its salts—green, red, violet. Iridium, a metal of the platinum family, is white, very hard, and brittle. It is the heaviest of all elements known with the exception of osmium. The standard meter in Paris is an alloy of platinum (90%) and iridium (10%). Iridium occurs, uncombined with platinum and other metals of this family in alluvial deposits. It is used in apparatus for high temperatures; alloyed with platinum for standard weights and measures; alloyed with osmium in tipping pens and compass bearings. Iridium black, prepared by exposing alcoholic solutions of the sulfate to light, is used as a catalytic agent. The most important salt is $IrCl_4$.

Iron (Anglo-Saxon, *iron*), Fe (L. *ferrum*); at. wt. 55.85; at. no. 26; m.p. 1535°C; b.p. 3000°C; sp. gr. 7.85–7.88 (20°C); valence 2, 3, or 6. Iron implements are said to have been made by the Egyptians 3000 B.C. The most common ore is *hematite* (Fe_2O_3), from which the metal is obtained by reduction with carbon. Iron is the most abundantly produced of the metals, though aluminum occurs in larger percentage in the earth's crust than iron. The pure metal, which is practically unknown in industry (although some grades of soft steel have a very high percentage of iron), is silver-white, very ductile and magnetic; the pure metal may be prepared by electrolytic deposition from ferrous sulfate, or by reduction of the pure oxide with hydrogen or aluminum. Pig iron is hard, brittle and fairly fusible, containing about 3% carbon and varying amounts of sulfur, silicon manganese and phosphorus; wrought iron is tough, grayish-white and malleable, having usually a fibrous structure, very infusible, with only a few tenths per cent or less of carbon; steel is a solid solution of iron carbide in iron with a carbon content usually below 2%. Iron is the cheapest metal known. Alloying with other metals has greatly improved the properties and widened the use of steel.

Krypton (Gr. *kryptos*, hidden), Kr; at. wt. 83.8; at. no. 36; m.p. −156.6°C; b.p. −152.9°C; density 3.708 g/l (0°C); valence 0. Discovered in 1898 by Ramsay and Travers in the residue left after liquid air had nearly boiled away. There is one part of krypton in a million parts of air; it is an inert, rare, gaseous element, and is characterized by brilliant green and yellow lines in its spectrum.

Lanthanum (Gr. *lanthano*, to lie hidden, La; at. wt. 138.92; at. no. 57; m.p. 826°C; b.p. . . . ; sp. gr. 6.155; valence 3. Occurs in the cerium group of the rare earth metals, lanthana being separated from ceria by Mosander in 1839. It is found in ores *cerite, orthite* and *monazite*. The white metal is prepared from the chloride by treatment with sodium, or by electrolysis of a fused bath of lanthanum and potassium chlorides and calcium fluoride. Lanthanum resembles iron in its physical properties, burning brilliantly in the air to form La_2O_3. Salts are colorless.

Lead (Anglo-Saxon *lead*), Pb (L. *plumbum*); at. wt. 207.21; at. no. 82; m.p. 327.4°C; b.p. 1620°C; sp. gr. 11.35 (20°C); valence 2 or 4. Long known; mentioned in Exodus. Lead is obtained chiefly from galena (PbS) by a roasting process. It is a bluish-white metal of bright luster, very soft, highly malleable; has slight tenacity, is ductile and a poor conductor of electricity; lasts very long, since lead pipes bearing the insignia of Roman emperors, used as drains from the baths, are still in service. It is also used as containers for corrosive liquids, as in sulfuric acid chambers; it may be toughened by the addition of a small percentage of antimony or other metal. Its alloys include solder, type metal and various antifriction metals. Great weights of lead both as the metal and as the dioxide are used in storage batteries. Much metal also goes into cable covering, plumbing, ammunition, and in the manufacture of lead tetraethyl, used generally as an anti-knock in gasoline. White lead, the basic lead carbonate, sublimed white lead ($PbSO_4$), chrome yellow ($PbCrO_4$), red lead (Pb_3O_4) and other lead compounds are extensively used in paints. The nitrate and the acetate are soluble salts. Lead salts are used in medicine, as antiseptics and astringents. Care must be used in both medicine and industry as lead is a cumulative poison.

Lithium (Gr. *lithos*, stone), Li; at. wt. 6.940; at. no. 3; m.p. 186°C; b.p. 1336 ± 5°C; sp. gr. 0.534 (20°C); valence 1. Discovered by Arfvedson in 1817. Lithium is the lightest alkali metal; never found free in nature, traces of it occur in nearly all igneous rocks and in the waters of many mineral springs. *Lepidolite*, *spodumene*, *petalite* and *amblygonite* are the more important minerals containing it. The metal is produced from the fused chloride electrolytically. It has the highest specific heat of any solid element. It is the lightest metal known, soft and white; burned in air it forms Li_2O; its salts are analogous to those of sodium and potassium. The carbonate and citrate were used in medicine to remove uric acid from the body, since lithium urate is soluble. To a limited extent the metal is used industrially in various alloys increasing tensile strength and resistance to corrosion. In the flame test for lithium a brilliant crimson is given.

Lutetium (*Lutetia*, ancient name of Paris—sometimes called cassiopeium by the Germans), Lu; at. wt. 174.99; at. no. 71; m.p. . . . . ; b.p. . . . . . . ; sp. gr. . . . . . . ; valence 3 or 4. In 1907 Urbain and in 1908 von Welsbach described a process by which Marignac's ytterbium (1879) could be separated into the two elements, ytterbium (neoytterbium) and lutetium. Both elements occur in very small amounts in nearly all minerals containing yttrium. Charles James of New Hampshire prepared lutetia independently. This rare earth has little practical use. The oxide is white and its salts are colorless.

Magnesium (Magnesia, district in Thessaly), Mg; at. wt. 24.32; at. no. 12; m.p. 651°C; b.p. 1107°C; sp. gr. 1.74 (20°C); valence 2. Compounds long known, recognized by Black as an element in 1755, isolated by Davy in 1808, prepared in coherent form by Bussy in 1831. Magnesium is one of the most abundant metals and the eighth element in estimated amount in the earth's crust. It does not occur uncombined but many carbonates and silicates contain considerable percentages, while soluble sulfate and chloride are found in mineral springs and in the ocean. It has been obtained by the electrolysis of the fused chloride; this method has been used for commercial production in the U. S. since 1916, using brines from wells and recently sea water from the Gulf of Mexico also. Electrothermic methods have also been proposed, being difficult because the metal combines when heated both with oxygen and with nitrogen. Recognition of its importance in war caused the one producing company in the U. S. in 1939 to expand its productive capacity six fold. By government direction this was expected to be increased ten times. However, the world output in 1947 was only 20,000 tons, as the postwar demand is far below expectations. It is a light, white, and fairly tough metal; tarnishes slightly in air, and as ribbon, wire or powder ignites on heating, burning with a dazzling white flame. It is useful in flash-light photography, flares and for pyrotechnics, including incendiary bombs. It is one-third lighter than aluminum and in its alloys is essential for airplane construction. The first metallic magnesium produced commercially sold for $10 a pound; the price is now less than 30¢. Important compounds are the oxide, chloride, sulfate and citrate, which find use in medicine. In Grignard's reaction, organic magnesium compounds are useful.

Manganese (L. *magnes*, magnet), Mn; at. wt. 54.94; at. no. 25; m.p. 1260°C; b.p. 1900°C; sp. gr. 7.2 (20°C); valence 2, 3, 4, 6, or 7. Recognized by Bergman, Scheele and others, discovered by Gahn in 1774 by reduction of dioxide with carbon. Manganese minerals are widely distributed, oxides, silicates and carbonates being most common. Pyrolusite (MnO_2) and psilomelane are common ores. The metal is obtained by reduction of the oxide with sodium, magnesium, aluminum, or by electrolysis. It is gray-white, resembling iron, but is harder and very brittle. Its alloys with iron, copper and nickel are important. The mineral, *pyrolusite*, has been used since very early times to give color to glass; a smaller amount gives a weaker amethyst color which removes the greenish color due to iron and other impurities and makes colorless glass. Other compounds are the chloride, sulfate and permanganate, which is used as an antiseptic and in quantitative analysis because of its oxidizing power. The U. S. production is only a small fraction of the consumption. Of this 95% goes into steel alloys with only 5% into chemicals and dry batteries.

*__Mercury__ (Planet Mercury), Hg (*hydrargyrum*, liquid silver); at. wt. 200.61; at. no. 80; m.p. −38.87°C; b.p. 356.9°C; sp. gr. 13.546 (20°C); valence 1 or 2. Known to ancient Chinese and Hindus; found in Egyptian tombs of 1500 B.C. Mercury, the only common metal liquid at ordinary temperatures, occurs free in nature, but the chief source is the sulfide (*cinnabar*, HgS), from which it may be obtained by heating in a current of air. It is a heavy silver-white, shining metal, a fair conductor of heat and electricity, having a regular coefficient of expansion. These properties make it generally useful in the laboratory for thermometers, barometers and many other instruments. It tarnishes but slightly in the air except when heated to near the boiling point, where it is slowly converted to the oxide (HgO), from which the oxygen is set free again at higher temperatures. Mercury forms alloys, called *amalgams*, with many metals. The most important salts are mercuric chloride ($HgCl_2$, violent poison and antiseptic), mercurous chloride (HgCl, calomel laxative of medicine), mercury fulminate ($Hg(ONC)_2$, a detonator widely used in explosives), and mercuric sulfide (HgS, vermilion, a high grade red paint). Organic mercury compounds are likewise important.

Molybdenum (Gr. *molybdos*, lead), Mo; at. wt. 95.95; at. no. 42; m.p. 2620°C; b.p. 4800°C; sp. gr. 10.2; valence 2, 3, 4, 5, or

---

* See new element Mendelevium at end of table.

6. Recognized by Scheele in 1778; prepared in an impure form in 1782 by Hjelm. Molybdenum does not occur native, being obtained from *molybdenite* (MoS_2) and from *wulfenite* ($PbMoO_4$). The metal is prepared by the reduction of the oxide with carbon, usually in the electric furnace. It is a very hard silver-white metal; it is widely used in the manufacture of certain grades of tool steel, boiler plate, rifle barrels and large cranks, as it increases toughness and tensile strength. Being softer and more ductile than tungsten it is invaluable for the filaments, grids and screens for radios.

Neodymium (Gr. *neos*, new and *didymos*, twin), Nd; at. wt. 144.27; at. no. 60; m.p. 840°C; b.p. . . . . . . ; sp. gr. 6.95; valence 3. In 1843 Mosander reported the supposed element didymium obtained from *cerite*. In 1885 von Welsbach separated didymium into two new elements, neodymium and praseodymium by repeated fractionation of ammonium didymium nitrate. Neodymium is a faintly yellow metal, belonging to the rare earths, and forming a series of pink salts with a characteristic absorption spectrum.

Neon (Gr. *neos*, new), Ne; at. wt. 20.183; at. no. 10; m.p. −248.67°C; b.p. −245.9°C; density 0.8990 g/l (0°C); valence 0. Discovered by Ramsay and Travers in 1898. Neon is a gaseous element present in the atmosphere to the extent of 18 parts per million. It is obtained by liquefaction of air and separated from the other elements by fractional distillation. It is an inert element forming no compounds. Neon glows red-orange in a vacuum tube and is therefore widely used in electric signs and beacons. Its spectrum is marked by pronounced red and green lines.

****Neptunium** (Planet Neptune, next to Uranus in solar system), Np; at. wt. 237; at. no. 93; valence 4, 5, or 6. Discovered by tracer technique by E. M. McMillan and P. H. Abelson at the University of California in 1940. This Np 93^{239} is the decay product of the 23 minute U^{239} formed by the radioactive neutron capture in U^{238}. Amounts used were so small as to be unweighable, so that radioactivity rather than chemical analysis had to be basis of work. By greatest care and most skillful work the elements and its pure compounds were prepared and studied. By loss of a β particle Np^{239} becomes Pn^{239}, which is fissionable.

Nickel (Sw. abbr. of *kopparnickel*, false copper), Ni; at. wt. 58.71; at. no. 28; m.p. 1455°C; b.p. 2900°C; sp. gr. 8.90 (20°C); valence 2 or 3. Discovered by Cronstedt in 1751. Nickel is obtained chiefly from the nickel bearing *pyrrhotite* of Ontario and the *garnierite* (hydrated silicate of nickel, iron and magnesium found in New Caledonia) by roasting to the oxide, which is then reduced with carbon or carbon monoxide, volatile nickel carbonyl being formed and then decomposed by heat. The metal is hard, malleable, ductile and tenacious, of a white color, somewhat magnetic, a fair conductor of heat and electricity; it belongs to the iron-cobalt group of metals. Nickel is chiefly valuable for the alloys it forms; coinage with 75% of copper, Monel metal with copper and iron, nickel steel for armor plates and burglar proof safes, invar, constantan, permalloy, nichrome, platinite and others. Nickel plate by electrodeposition is used as a protective coating for metals, and finely divided nickel as a catalyst in the hydrogenation of vegetable oils. Early in this century Edison developed a storage battery, using an alkaline solution with nickel hydroxide and iron oxide. The sulfate and the oxides, NiO and Ni_2O_3, are important compounds.

** For further description see following section "Transuranium Elements."

Niobium (Niobe, daughter of Tantalos) Nb; (or Cb); at. wt. 92.91; at. no. 41; m.p. 2500°C; b.p. 3700°C; sp. gr. 8.4 (20°C); valence 3 or 5. Discovered in 1801 by Hatchett in an ore sent to England more than a century before by John Winthrop, first governor of Connecticut. Metal prepared by Blomstrand, who reduced the chloride by heating in hydrogen in 1864. Niobium is a rare metallic element, found as *columbite* in pegmatite veins, volcanic intrusions through the earth's crust. Added to stainless steel this metal by combining with carbon preserves the corrosion resistance even when heated. This use has greatly increased the demand for the metal now obtained from an African ore. After removing tin from this ore, the residue is reduced with silicon or aluminum in an electric furnace, giving ferro-niobium, suited to steel making. The metal is gray; it forms an acid oxide, Nb_2O_5, from which salts are derived.

Nitrogen (L. niter forming), N; at. wt. 14.008; at. no. 7; m.p. −209.86°C; b.p. −195.8°C; density 1.2506 g/l; sp. gr. liquid 0.808 (−195.8°C) solid 1.026 (−252°C) valence 3 or 5. Discovered by Daniel Rutherford in 1772. Nitrogen makes up 78% of the air by volume, the estimated amount in the atmosphere being more than 4000 billion tons; from this inexhaustible source it can be obtained by liquefaction and fractional distillation. The element is so inert that Lavoisier named it *azote*, without life, yet its compounds are so active as to be most important in foods, poisons, fertilizers, and explosives. In 1947–48 there were the largest production, consumption, and importation of nitrogen compounds yet recorded. Nitrogen is also prepared easily by heating a water solution of ammonium nitrite (made from ammonium chloride and sodium nitrite). Nitrogen is colorless, odorless and generally inert element. When heated it will combine directly with magnesium, lithium or calcium; when mixed with oxygen and subjected to electric sparks it forms first nitric oxide (NO) and then the peroxide (NO_2); when heated under pressure with a catalyst with hydrogen ammonia is formed (Haber process). The ammonia thus formed is of the utmost importance, and may be oxidized to nitric acid (Ostwald process). Sodium and potassium nitrates are formed by the decomposition of organic matter with compounds of the metals present; in certain dry areas these saltpeters are found in quantity. The chief compounds are ammonia, nitric acid, the nitrates, the five oxides (N_2O, NO, N_2O_3, NO_2, and N_2O_5) as well as very many organic substances.

***Osmium** (Gr. *osme*, odor) Os; at. wt. 190.2; at. no. 76; m.p. 2700°C; b.p. above 5300°C; sp. gr. 22.48 (20°C); valence 2, 3, 4, or 8. Discovered in 1803 by Tennant in the residue left when crude platinum is dissolved by *aqua regia*. Osmium occurs in *iridosime* and in platinum bearing river sands of the Urals, North America and South America. The metal is bluish-white, hard and crystalline, belonging to the platinum family. It is the heaviest known form of matter and is very infusible. When heated in air it is oxidized to OsO_4 with a pungent, irritating and poisonous vapor, which is easily reduced by organic matter. The oxide gives the element its name, and is useful in making microscopic slides. The metal has been used in making lamp filaments and with iridium forms the alloy osmiridium, which is very hard, suggesting its use for tipping gold pen points and for fine machine bearings.

Oxygen (Gr. *oxys*, acid, and *genes*, forming, acid former), O; at. wt. 16.0000; at. no. 8; m.p. −218.4°C; b.p. −183.0°C; density 1.429 g/l (0°C); sp. gr. liquid 1.14 (−182.96°C); valence 2. Discovered in 1774 by Priestley, who obtained it by heating mercuric oxide, using the sun's rays with a burning glass; independently by Scheele from other sources. Oxygen as a gaseous element forms 21% of the atmosphere by volume, from which it can be obtained by liquefaction and fractional distillation. Free and in compounds it makes up approximately one-half of the total material on the surface of the earth, forming by weight more than one-fifth of the air, about two-thirds of the human body and eight-ninths of the water, with a very high percentage in the minerals of the earth's crust. In the laboratory it is usually prepared by the electrolysis of water, or by heating potassium chlorate with manganese dioxide as a catalyst. The critical temperature and pressure are −118°C and 50 atmospheres. The gas is colorless, odorless, and tasteless; the liquid and solid forms are a pale blue color and are magnetic, but much less so than iron. Oxygen is very reactive, capable of combining with all the other elements except the inert gases in Group O and fluorine. Its atomic weight is the standard of comparison for the atomic weight of each of the other elements. It is used with combustible gases in the oxyhydrogen and oxy-acetylene flames. It is essential for respiration of all animals and for practically all combustion; in medicine it is used to aid respiration.

Palladium (Planetoid Pallas), Pd; at. wt. 106.7; at. no. 46; m.p. 1549.4°C; b.p. 2200°C; sp. gr. 12.16 (20°C); valence 2 or 4. Discovered in 1803 by Wollaston. Palladium occurs with platinum and is obtained by ignition of the precipitated cyanide. It is a steel-white metal of the platinum family; does not tarnish in air and has the property of taking up large volumes of hydrogen with the formation of the hydride. It is used in the construction of non-magnetic watches and parts of delicate balances and in surgical instruments. Both the metal and its compounds are used as catalysts. The most important compound is the chloride, $PdCl_2$.

---

* See new element Nobelium at end of table.

Phosphorus (Gr. *phosphoros*, light bearing), P; at. wt. 30.975; at. no. 15; m.p. 44.1°C; b.p. 280°C; sp. gr. yellow 1.82, red 2.20; valence 3 or 5. Discovered in 1669 by Brand, who prepared it from urine. Phosphorus may be prepared in three allotropic forms; white or yellow, red, black. Never found free in nature, it is widely distributed in combination in minerals, the most important being the *apatites* ($3Ca_3(PO_4)_2.CaF_2$ and $3Ca_3(PO_4)_2.CaCl_2$), which are the chief ingredients of commercial phosphates derived from South Carolina, Florida, Canada and Spain; it is an essential ingredient of all cell protoplasm, nervous tissue and bones. It may be obtained from phosphates by treatment with dilute sulfuric acid to form *o*-phosphoric acid, the concentrated solution of which is mixed with crushed charcoal or coke and dried; on heating this mixture in retorts, the phosphorus distils and is condensed. It is also prepared by heating crude phosphate with sand and coke in the electric furnace, the phosphorus distilling off. Ordinary phosphorus is a waxy solid, which is colorless when very pure, insoluble in water but soluble in carbon disulfide. It takes fire spontaneously in air, burning to the pentoxide; it is very poisonous. When heated in its own vapor to 250°C it is converted into the red variety, which does not glow in the air, does not ignite spontaneously, and is not poisonous. The production of phosphorus and its compounds has increased very rapidly in recent years; phosphoric acid is replacing sulfuric acid in the treatment of natural phosphates to make them soluble for use as fertilizers, since this causes a great increase in the percentage of P_2O_5 present and available. World wide demand for fertilizer materials has caused record phosphate production in the years following World War II. Organic compounds are increasing in number and in importance. Di- and tri-sodium phosphates are used as detergents in large quantities, while hexametaphosphate is in frequent use for the prevention of boiler scale and of corrosion in pipes and boiler tubes. Other important compounds are the phosphoric anhydride, used as a toxic smoke in warfare and made from burning phosphorus, and the chlorides, PCl_3 and PCl_5.

Platinum (Sp. *platina*, little silver), Pt; at. wt. 195.09; at. no. 78; m.p. 1773.5°C; b.p. 4300°C; sp. gr. 21.37 (20°C); valence 2 or 4. Discovered in South America by Ulloa in 1735 and by Wood in 1744. Platinum usually occurs native, accompanied by small quantities of iridium, osmium, ruthenium, rhodium and palladium, all belonging to the same group of metals. These are usually found in alluvial deposits in the Ural mountains, in Colombia and in certain western American states. Sperrylite ($PtAs_2$) occurring with nickel bearing deposits in Canada is the source of a considerable weight of the platinum metals, which are recovered as by-products in refining the nickel. The heavy nickel production offsets the fact that there is only one part of the platinum metals in two million parts of ore. Platinum is a tin-white metal of metallic luster, tenacious, malleable and ductile; it is welded at a red heat; has a coefficient of expansion approximately equal to that of glass. The metal does not oxidize in air at any temperature, but is corroded by halogens, cyanide, sulfur and caustic alkalies; it is insoluble in hydrochloric or nitric acids, but dissolves when they are mixed as *aqua regia*, forming chloroplatinic acid (H_2PtCl_6), a very important compound. The metal is extensively used in jewelry, in wire and vessels for laboratory use, as well as many valuable instruments; in finely divided state it is an excellent catalyst, having long been used in the contact process for sulfuric acid, of which it does not now have a monopoly. The price of platinum has varied widely, the metal being used more than a century ago to adulterate South American gold; in 1920 platinum was nearly eight times as valuable as gold, but is much less now.

[**] **Plutonium** (Planet Pluto, next in order beyond Uranus and Neptune in solar system), Pu; at. wt. 242; at. no. 94; valence 3, 4, 5, or 6. Discovered by G. T. Seaborg, E. M. McMillan, A. C. Wahl, and J. W. Kennedy at the University of California late in 1940 by the deuteron bombardment of uranium. This gave Np^{238}, which decays after a two day half-life to an alpha emitting isotope of element 94 with a half-life of about 50 years. A more important isotope of plutonium—94^{239}—was discovered in the spring of 1941 by G. T. Seaborg, E. Segré, J. W. Kennedy, and E. O. Lawrence at the University of California. This is the daughter of 2.3 day neptunium with a half-life of 24,000 years, and is fissionable. The element and pure compounds were prepared. Its study was the basis of the atomic energy plant at Hanford, Washington, with a stepup of 10^{10} in the plans prepared.

Polonium (Poland, native country of Mme. Marie Curie), Po; at. wt. approximately 210; at. no. 84. First element discovered by Mme. Curie (1898) in seeking cause of radioactivity of pitchblende from Joachimisthal, Bohemia. The electroscope, claimed to be 500,000 times more sensitive than the spectroscope, showed it separating with the bismuth. Polonium is also called Radium F. (See Radioactive Elements.)

Potassium (English *potash*), K (L. *kalium*); at. wt. 39.100; at. no. 19; m.p. 62.3°C; b.p. 760°C; sp. gr. 0.87 (20°C); valence 1. Discovered in 1807 by Davy, who obtained it from caustic potash (KOH); this was the first metal isolated by the aid of the electric current. The metal occurs abundantly, being the eighth element in the earth's crust, of which it makes more than 2%; most of its minerals are insoluble and the metal is obtained from them with great difficulty. Under certain conditions the salts of potassium have been concentrated from ancient ocean beds; before World War I the principal source of potassium was the mines of Stassfurt in Prussian Saxony from such beds. During this war the United States suffered a severe shortage of potassium salts, which form an essential constituent of fertilizers. Before World War II began the American production was sufficient to meet all needs; this supply came from mines in New Mexico, ancient lake beds in California and Utah, as a by-product from cement plant dust and from distillery waste. Recent fertilizer demand has greatly increased production and consumption of salts of potassium. Potassium is never found free but is obtained by the electrolysis of the hydroxide. On exposure to moist air it becomes coated with a film of the oxide, and so is preserved by immersion in kerosene or naphtha. It is a soft, bright, silvery metal belonging to the alkali group; dropped on water it evolves hydrogen which takes fire spontaneously, the flame being colored violet by the potassium. In some cases its compounds are more readily purified by crystallization than those of sodium; important are the hydroxide, carbonate, nitrate, chloride, chlorate, bromide, iodide, cyanide, sulfate, chromate, dichromate and silicate.

[**] For further description see following section "Transuranium Elements."

Praseodymium (Gr. *prasinos*, green, and *didymos*, twin), Pr; at. wt. 140.92; at. no. 59; m.p. 940°C; b.p. . . . . . ; sp. gr. 6.5 (20°C); valence 3, 4 or 5. In 1843 Mosander reported the rare earth didymia obtained from lanthana; in 1879 Lecoq de Boisbaudran isolated a new earth from didymia extracted from samarskite and called it samaria. Six years later Von Welsbach separated it into two earths which gave salts of different colors. Praseodymium is a faintly yellow metal from the cerium group of rare earths. It forms green salts with a characteristic spectrum. The metal has been prepared by the electrolysis of the chloride.

Promethium (Prometheus, who, according to mythology, stole fire from heaven) Pm; at. wt. uncertain, probably approximates 145; at. no. 61; valence doubtless 3. Discovery claimed in 1947 by J. A. Marinsky and L. E. Glendenen at Clinton National Laboratory, Oak Ridge, Tennessee. Work was done by fission of uranium and by neutron bombardment of neodymium. In 1902 Branner predicted the existence of an element between neodymium and samarium, and this was confirmed by Moseley in 1914. Since then several independent men or groups have claimed discovery and given a name, as illinium, florentium, cyclonium. Three milligrams each of the yellow chloride and of the rose nitrate have been exhibited. The name has not been finally and generally accepted.

Protactinium (Gr. *protos*, first), Pa; at. wt. 231; at. no. 91. The first element of the actinium series of radioactive elements was discovered by Soddy and Cranston and independently by Hahn and Meitner, both in 1917. Later Grosse prepared the pure pentoxide and from this in 1934 the metal. Protactinium has been called the "mother substance" or the "parent" of actinium, which it forms by the loss of an alpha particle, and the "patriarch" of the series; known also as ekatantalum and uranium X_2.

Radium (L. *radius*, ray) Ra; at. wt. 226.05; at. no. 88; m.p. 700°C; b.p. 1140°C; sp. gr. 5(?); valence 2. In the form of a salt ($RaBr_2$) it was first separated by M. and Mme Curie in 1898 from the *pitchblende* in North Bohemia, in which it occurs in about one part in three million. Isolated in 1911 by Mme. Curie and Debierne by the electrolysis of a solution of pure radium chloride, employing a mercury cathode; on distillation in an atmosphere of hydrogen this amalgam yielded the pure metal. The *carnotite* sands of Colorado furnished some radium, but richer ores were found in the Belgian Congo and later in the Great Bear Lake region of Canada, which is now the principal source. Radium is obtained commercially as the bromide or chloride. The metal is brilliant white, shows luminescence, alters very rapidly in contact with the air, decomposes water, and is somewhat more volatile than barium. The primary uses of the compounds are in producing self-luminous paints and in the treatment of certain types of cancer and skin affections. One gram of radium produces about 0.1 cubic millimeter of emanation per day; this is pumped from the radium and sealed in minute tubes, which are then applied to the diseased parts. Radium loses about 1% of its activity in 25 years, being transformed into elements of lower atomic weights. Study of radium and its activity has decidedly changed our ideas of the structure of the atom.

Radon (from radium, called niton at first, L. *nitens*, shining), Rn; at. wt. 222; at. no. 86; valence 0; m.p. −71°C; b.p. −61.8°C; sp. gr. 9.73 g/l. Discovered in 1900 by Dorn and called radium emanation; isolated in 1908 by Ramsay and Gray, who named it niton. They determined its density, finding it to be the heaviest gas known. It occupies the last place in the zero group of gases in the Periodic Table. Since 1923 it has been called radon to show its origin from radium. Thoron and actinon are isotopes. (See Radioactive Elements.)

Rhenium (L. *Rhenus*, Rhine), Re; at. wt. 186.22; at. no. 75; m.p. 3167 ± 60°C; b.p. . . . . . ; sp. gr. 20.53 (20°C); valence 4, 5, 6, 7, 8. One of the eka-manganeses (dwi-manganese) discovered in 1925 by Noddack, Tacke and Berg in the minerals columbite, tantalite, wolframite. It has been found also in molybdenum ore concentrates. Rhenium was detected with the aid of the Röntgen spectrum; its arc spectrum has been carefully studied by Meggers. The metal can be hot forged or rolled; dissolved readily in nitric acid, slowly in sulfuric, hardly at all in hydrochloric. The price of $10,000 per gram in 1928 dropped to $3 in 1930, the production increasing a thousand fold. This has made possible the use of the element as a catalyst for dehydrogenation and in connection with other metals.

Rhodium (Gr. *rhodon*, rose), Rh; at. wt. 102.91; at. no. 45; m.p. 1966 ± 3°C; b.p. above 2500°C; sp. gr. 12.5 (20°C); valence 1, 2, 3, or 4. Discovered in 1803 by Wollaston. Rhodium is a silver-white metal of the platinum family, occurring native with other members of this family in river sands in the Urals and in North and South America. The salts form red solutions. An alloy with platinum is used in connection with pure platinum to make thermojunctions in some forms of pyrometers. In electroplating it gives a surface unaffected by exposure to air or to strong acids or alkalies.

Rubidium (L. *rubidius*, dark red), Rb; at. wt. 85.48; at. no. 37; m.p. 38.5°C; b.p. 700°C; sp. gr. 1.53 (20°C); valence 1.

Discovered in 1861 by Bunsen and Kirchhoff by the use of the spectroscope in the mineral *lepidolite*. Rubidium occurs in small quantities, also, in some mineral springs and in the rare minerals, *castor* and *pollux*, found in Elba. It is prepared by the electrolysis of the cyanide. Rubidium is a soft, white, rare, metallic element of the alkali group; it forms salts similar to those of potassium and colors the flame dark red, when held in a burner.

Ruthenium (Ruthenia, Ukraine), Ru; at. wt. 101.1; at. no. 44; m.p. 2450°C; b.p. above 2700°C; sp. gr. 12.2 (20°C); valence 3, 4, 6 or 8. Discovered in 1844 by Klaus more than a century after the discovery of platinum. Ruthenium, belonging to the platinum group, occurs native with the other members of this group. The metal is hard, gray, and brittle; it forms red or brown salts; ruthenous chloride ($RuCl_3$) gives a characteristic fine black precipitate with water. Practical uses are needed to consume accumulated stocks.

Samarium (Samarski, a Russian), Sm; at. wt. 150.35; at. no. 62; m.p. above 1300°C; b.p. . . . . . ; sp. gr. 7.7–7.8; valence 2 or 3. Discovered in 1879 by Lecoq de Boisbaudran in the mineral *samarskite*, named in honor of a Russian mine official. Samarium is a grayish-white metal belonging to the cerium group of the rare earths, occurring in very minute quantities in *samarskite*, *cerite*, and certain Scandinavian minerals. The metal has been prepared by electrolysis of the fused anhydrous chloride. The yellow oxide, Sm_2O_3, dissolves in most acids to form yellow salts.

Scandium (Scandinavia), Sc.; at. wt. 44.96; at. no. 21; m.p. 1200°C; b.p. 2400°C, calculated; sp. gr. 3.02 (10°C) — ?; valence 3. Predicted by Mendeleeff on the basis of the Periodic Law; discovered by Nilson in 1879. By some scandium is placed in the rare earth group. The metal has not been isolated; it forms colorless salts derived from the oxide Sc_2O_3.

Selenium (Gr. *Selene*, moon), Se; at. wt. 78.96; at. no. 34; m.p. of gray form 220°C; b.p. 688°C; sp. gr. gray 4.8 (20°C); valence 2, 4 or 6. Discovered in 1817 by Berzelius associated with tellurium, named for the earth, hence the name chosen. The principal source of selenium is the flue dust obtained in burning pyrites in the manufacture of sulfuric acid. It is prepared in red amorphous form by reduction of selenic acid, and this on melting and keeping somewhat below the melting point becomes gray and crystalline. It is in the sulfur family, which it resembles both in the various forms of the element and in its compounds. The conductivity of electricity of the gray form increases with the brightness of the light with which it is illuminated. For this reason it can be used in photo-electric cells; its chief use is in the glass and ceramic industries. Red glass may contain colloidal selenium. It occurs in some soils in amounts sufficient to produce serious effects on animals feeding on plants grown in such soils.

Silicon (L. *silex*, flint), Si; at. wt. 28.09; at. no. 14; m.p. 1420°C; b.p. 2355°C; sp. gr. 2.42 (20°C); valence 4. First prepared by Berzelius in 1823. Next to oxygen, the most abundant element; characteristic of all abundant and important rocks except carbonates. It makes up about one-fourth of the crust of the earth. Silicon is not found free, it occurs chiefly as the oxide, silica (SiO_2) (sand, quartz, rock crystal, amethyst, agate, flint, jasper, opal, etc.) both free and in combination with the metallic oxides as silicates (granite, hornblende, asbestos, feldspar, clay, mica, etc). It is obtained as an amorphous brown powder on fusion of potassium fluosilicate with sodium or potassium; the crystalline form is obtained by passing silicon tetrachloride over melted aluminum in an atmosphere of hydrogen, or by heating potassium fluosilicate with zinc and sodium at a temperature just below the boiling point of zinc. Silicon is a non-metallic element resembling carbon in having several allotropic forms and in compounds formed. It is not attacked by acids except by a mixture of nitric and hydrofluoric acids; it is soluble in hot caustic potash or soda, evolving hydrogen and forming the corresponding silicate (K_2SiO_3 or Na_2SiO_3). Sodium silicate is of wide industrial importance. Glass, cement and clay working are called the silicate industries. An alloy of iron containing 14% of silicon is brittle, but extremely resistant to the action of acids, making it widely useful in the equipment of acid plants and in laboratory drains. Silicon carbide (SiC) is a most efficient abrasive. Silicones, organic compounds in which silicon replaces all or part of the carbon, are finding increasing uses.

Silver (Anglo-Saxon, *soelfor*), Ag (L. *argentum*); at. wt. 107.880; at. no. 47; m.p. 960.5°C; b.p. 1950°C; sp. gr. 10.50 (20°C); valence 1. Known to ancients. Silver occurs native and in ores in combination with many non-metallic elements, as *argentite* (Ag_2S) and horn silver (AgCl); lead and copper ores yield considerable silver. It is obtained from its ores by smelting with lead or copper, by cyanidation, or by amalgamation with mercury. The metal is pure white having a brilliant luster, a little harder than gold and excelled only by that metal in malleability and ductility; it excels all other metals as a conductor of heat and electricity; it undergoes no change in water or pure air, but absorbs 22 times its volume of oxygen when melted, which is again expelled on cooling; it tarnishes in the vapors of sulfur compounds forming the black sulfide (Ag_2S). The most important compounds of silver are the nitrate ($AgNO_3$), or lunar caustic, the oxide (Ag_2O), and the halides (AgCl, AgBr), which darken on exposure to light, which is the basis of photography. A dilute solution of silver nitrate is used in medicine as an antiseptic. The metal is extensively used for coins, in jewelry and in tableware.

Sodium (English, *soda*), Na (L. *natrium*); at. wt. 22.991; at. no. 11; m.p. 97.5°C; b.p. 880°C; sp. gr. 0.971 (20°C); valence 1. Long recognized in compounds; first isolated by Davy in 1807 by electrolysis. Sodium is the most abundant of the alkali metals, being the seventh element in amount in the crust of the earth. Sodium chloride is the most common compound, but it occurs in many others. Never found free, it is obtained by the electrolysis of the chloride or hydroxide; it is a soft, bright, silvery metal. On exposure to moist air it becomes coated with a film of the oxide or hydroxide, and is preserved by immersing in kerosene or naphtha. It decomposes water with the formation of hydrogen and sodium hydroxide; it burns in air with the formation of the peroxide (Na_2O_2); it is used for the reduction of organic compounds, in the preparation of the peroxide and cyanide, and for keeping mercury clean and active in gold extraction. Soap is generally a sodium salt of certain fatty acids. Its compounds are of the widest industrial importance, being manufactured in hundreds of thousands of tons annually. Some of these are common salt ($NaCl$), soda ash (Na_2CO_3), baking soda ($NaHCO_3$), caustic soda ($NaOH$), Chile saltpeter ($NaNO_3$), di- and tri-sodium phosphates, sodium thiosulfate (hypo, $Na_2S_2O_3.5H_2O$), borate (borax, $Na_2B_4O_7.10H_2O$).

Strontium (Strontian, town in Scotland), Sr; at. wt. 87.63; at. no. 38; m.p. 800°C; b.p. 1150°C; sp. gr. 2.54 (20°C); valence 2. Discovered by Crawford, a Scotchman in 1790; metal isolated by Davy by electrolysis in 1808. Strontium is found chiefly in *celestite* ($SrSO_4$) and *strontianite* ($SrCO_3$). Prepared by the electrolysis of the fused chloride, it resembles metallic calcium in its properties; it is a hard silver-white metal. The salts are generally soluble in water with the exception of the sulfate, phosphate and carbonate; they impart a brilliant, blood-red color to the flame, and are used in pyrotechny for red fire. Strontium salts are also used in beet sugar refining.

Sulfur (L. *sulfur*), S; at. wt. 32.066; at. no. 16; m.p. rhombic 112.8°C, monoclinic 119.0°C; b.p. 444.6°C; sp. gr. rhombic 2.07, monoclinic 1.957 (20°C); valence 2, 4, or 6. Known to the ancients. Formerly obtained from the vicinity of volcanoes, active or extinct, since the beginning of this century the chief supply has come from wells sunk into the salt domes along the Gulf coast. The Frasch process of concentric pipes with great quantities of superheated water has been used to melt and raise the sulfur, giving a product of very high purity. Sulfur is widely distributed in nature in free form; in sulfides, as iron (*pyrites*), lead (*galena*), zinc (*blende*), mercury (*cinnabar*) and antimony (*stibnite*); in sulfates, as calcium (*gypsum*), magnesium (*Epsom salt*), strontium (*celestite*) and barium (*barite* or *heavy spar*). Sulfur is a pale yellow, odorless, brittle solid, which is insoluble in water, soluble in carbon disulfide. It occurs in two crystalline forms and an allotropic form known as plastic sulfur, which reverts to the crystalline form on standing; a finely divided form known as flowers of sulfur is obtained by sublimation. It readily forms compounds known as sulfides with many elements. Sulfur is a component of black gunpowder, is widely used in the vulcanization of rubber and as a fungicide. A tremendous tonnage is used after burning to form sulfur dioxide in the manufacture of sulfuric acid, the most important manufactured chemical, and in the processes for making wood pulp for paper; sulfur dioxide is also used in fumigation and in the bleaching of dried fruits. The element is a good electrical insulating agent, and organic compounds containing sulfur are very important.

Tantalum (Gr. *Tantalos,* mythological character) Ta; at. wt. 180.88; at. no. 73; m.p. 2996°C; b.p. above 4100°C; sp. gr. 16.6; valence 3 or 5. Discovered in 1802 by Ekeberg. Tantalum occurs principally in the mineral *tantalite* ($FeTa_2O_6$), very similar to columbite, and is prepared by the reduction of K_2TaF_7 with hydrogen followed by fusion in a vacuum. It can be drawn into a wire with a very high point of fusion and great tenacity, which has been used in the construction of filaments for incandescent lamps; it has been generally replaced by tungsten, but tantalum is still used when lamps have to resist more than ordinary vibration. It is also used to alloy with other metals. Tantalum finds use in radio and radar tubes, as a catalyst in the manufacture of synthetic rubber, in carbide cutting tools, in aerial camera lenses, in corrosion resistant chemical equipment, in surgical wire and skull plates. The metal is soluble in fused alkalies, insoluble in acids; especially suited for plant work with halogens, hydrochloric acid, and *aqua regia.* The common oxide is Ta_2O_5.

Technetium (Gr. technetos, artificial), Tc; at. wt. 99; at. no. 43; valence 6 and 7 observed. First produced in 1937 by C. Perrier and E. Segré at the University of California by bombarding molybdenum with deuterons or neutrons. Wu and Segré later found that this element can be isolated in large amounts from the fission products of uranium. The name was given "in recognition of the fact that technetium is the first artificially made element." A pink colored sample of mixed compounds of technetium in its plus six and plus seven valence states was exhibited in 1948.

Tellurium (L. *tellus,* earth), Te; at. wt. 127.61; at. no. 52; m.p. 452°C; b.p. 1390°C; sp. gr. 6.24 (20°C); valence 2, 4, or 6. Discovered by Muller von Richenstein in 1782; named by Klaproth in 1798. Tellurium is found native and as the telluride of gold and other metals. It is obtained by reduction of telluric oxide and forms a powder of grayish-white, metallic appearance. It is a semi-metallic element of the sulfur group and forms tellurides with hydrogen and metals similar to the sulfides; the compounds H_2TeO_3 and H_2TeO_4 are only slightly acidic. The inhalation of the vapors of tellurium produces the very offensive "tellurium breath." It is used as a coloring agent in glass, giving a blue to brown color. Certain alloys give high electrical resistance. Addition of less than a tenth of one per cent to lead greatly increases its strength and hardness.

Terbium (Ytterby, village in Sweden), Tb; at. wt. 158.93; at. no. 65; m.p. . . . . ; b.p. . . . . . ; sp. gr. . . . . . ; valence 3. Discovered by Mosander in 1843 from *gadolinite.* Terbium is a metal of the rare earths; in order of discovery it falls in the Yttria group; the metal has not been isolated. It yields a white oxide Tb_2O_3, and forms trivalent salts. Its name together with the names yttrium, ytterbium, and erbium, are all derived from the little Swedish town, Ytterby, where the rare earth minerals were first found.

Thallium (Gr. *thallos*, budding twig), Tl; at. wt. 204.39; at. no. 81; m.p. 302°C; b.p. 1457 ± 10°C; sp. gr. 11.85 (20°C); valence 1 or 3. Discovered by the use of the spectroscope in 1861 by Crookes, who isolated the metal in 1862. Lamy also isolated the metal in 1862. Thallium occurs in *pyrites* and is prepared from the flue dust of sulfuric acid works. The metal is obtained by heating thallium iodide with metallic sodium; it resembles lead, having a hardness of 1.2 compared with 1.5 for lead; the malleability is high and the tenacity is low; there are two allotropic forms with a transition temperature of 226°C; it is a poor conductor of electricity, tarnishes in air forming the oxide Tl_2O, or the hydroxide TlOH in the presence of water. The element is displaced from solutions of its salts by zinc. Because of its resemblance to both the alkali metals and to the metals of Group III, thallium has been called the "paradoxical metal" and the "bird-beast metal." Its salts are poisonous, and are used in the control of rodents such as squirrels.

Thorium (*Thor*, Scandinavian god of war), Th; at. wt. 232.05; at. no. 90; m.p. 1845°C; b.p. above 4500°C; sp. gr. 11.3 (20°C); valence 4. Discovered by Berzelius in 1828. Thorium occurs chiefly in *thorite* ($ThSiO_4$) and other rare minerals. In the U. S. it is obtained chiefly from *monazite*, which contains from 3 to 9% of ThO_2. The free element has been prepared by heating the double chloride or fluoride of thorium and potassium with metallic sodium or potassium; it is a heavy, gray, difficultly fusible metal. It burns brightly in oxygen to form ThO_2, which is also obtained on heating the nitrate, a reaction of which use is made in the manufacture of incandescent gas mantles. Thorium emits radiations similar to but not identical with those of radium.

Thulium (*Thule*, Northland), Tm; at. wt. 168.94; at. no. 69; m.p. . . . . ; b.p. . . . . . ; sp. gr. . . . . . . ; valence 3. Discovered in 1879 by Cleve; pure thulia was prepared in 1911 by James. Thulium is in the yttrium group of the rare earth metals in order of discovery and belongs to the erbium family, which includes dysprosium, holmium and erbium also. They are obtained from certain rare minerals occurring in granite or pegmatite veins. These elements are characterized by their absorption spectra and the formation of highly colored salts; they form basic oxides of the type M_2O_3 with the following order of increasing basicity; thulium, erbium, holmium and dysprosium. The free elements have not been isolated.

Tin (Anglo-Saxon *tin*), Sn (L. *stannum*); at. wt. 118.70; at. no. 50; m.p. 231.89°C; b.p. 2270°C; sp. gr. gray 5.75, rhombic 6.55, tetragonal 7.31 (20°C); valence 2 or 4. Known to the ancients. Tin is found chiefly in the mineral *cassiterite* (SnO_2), found in association with granitic rocks, almost none found in the U. S. It is obtained by roasting to remove sulfur and arsenic and smelting with powdered anthracite in a reverberatory furnace. A smelter built in Texas to handle Bolivian ores during World

War II continued in operation after 1945. Tin is found in several varieties; as ordinarily used it is a silver white metal, malleable and somewhat ductile with a low tenacity and highly crystalline structure. Due to a breaking of these crystals, the "tin cry" is heard when a bar is bent. Crystalline tin changes to gray tin at low temperatures, the speed of change reaching a maximum at −50°C. Ordinarily it takes a high polish and is used to coat other metals to prevent corrosion or other chemical action. Such tin plate over steel is used in the so called tin can for preserving food; enough is used in America each year to make a 100 foot wide belt around the earth at the equator. When heated in air, tin forms SnO_2, which is feebly acid, forming stannate salts with basic oxides. The most important salt is the chloride ($SnCl_2.2H_2O$), which is used as a reducing agent and as a mordant in calico-printing. Alloys of the metal are very important, including solder, type metal, fusible metal, pewter, bronze and bell metal.

Titanium (L. *Titans*, the first sons of the Earth, myth.), Ti; at. wt. 47.90; at. no. 22; m.p. 1800°C; b.p. above 3000°C; sp. gr. 4.5 (20°C); valence 2, 3, or 4. Discovered by Gregor in 1791; named by Klaproth in 1795; pure metal prepared in 1910 by Hunter by heating $TiCl_4$ with sodium in a steel bomb. Titanium is almost invariably present in igneous rocks and the sedimentary material derived from them, occurring as the oxide (TiO_2), in titanates and with many iron ores. The metal is prepared by heating the oxide with aluminum or by electrolysis of the oxide dissolved in fused calcium chloride. It is a lustrous white metal in the same group with tin; it burns in air and is the only element which burns in nitrogen. The most important compounds are the oxide (TiO_2), which is feebly acidic and from which the titanates are derived; the halides (TiX_4), some of which are volatile; and the nitrides (Ti_2N_2, Ti_3N_4), metallic in appearance. The oxide is used in high grade white pigments of great opacity and covering power. The metal is used in steel alloys to increase strength.

Tritium, an isotope of hydrogen—see Hydrogen.

Tungsten (wolframite) W; (G. Wolfram); commonly known as tungsten (Sw. heavy stone); at. wt. 183.86; at. no. 74; M.P. 3370°C; b.p. 5900°C; sp. gr. 19.3 (20°C); valence 2, 4, 5, or 6. Recognized and named by Scheele in 1781; discovered by d'Elhujar brothers in 1783. Wolfram occurs in tungstates as *wolframite* ($FeWO_4$), *scheelite* ($CaWO_4$), *hübnerite* ($MnWO_4$). The metal is obtained by reduction of the oxide (WO_3) with hydrogen, carbon or aluminum. It is hard, brittle, nonmagnetic and forms the oxide when heated in the air. The only solvent for tungsten is a mixture of nitric and hydrofluoric acids. Because its melting point is higher than that of any other known metal, its vapor pressure is extremely low, making it useful for electric wiring for furnaces, targets of X-ray tubes, contacts, arcing points; its higher electrical efficiency causes its almost exclusive use in light filaments. About 90% of the world's production is used in steel manufacture, its various steel alloys being used in armor plate, projectiles and high speed cutting tools. Salts of tungsten are used in chemical, pigment and tanning industries.

Uranium (Planet Uranus), U; at. wt. 238.07; at. no. 92; m.p. about 1150°C; b.p. . . . . . . ; sp. gr. 18.68 (20°C); valence 3, 4 or 6. Discovered by Klaproth in *pitchblende* in 1789; metal first prepared in 1841 by Peligot by reducing the chloride with metallic potassium. This method is still used. The chief ore is *uraninite*, or *pitchblende*, uranous uranate, $U(UO_4)_2$; the metal is hard, white, heavy. Uranium is used chiefly in compounds which give a canary-yellow fluorescent glass and a black pigment for china painting; its compounds are used in photography. Of the generally recognized elements it has the highest atomic weight and is the last in the Periodic Table. Uranium compounds are radioactive. It has been the most important element in work on nuclear energy and the atomic bomb.

Vanadium (Scandinavian goddess, *Vanadis*), V; at. wt. 50.95; at. no. 23; m.p. 1710°C; b.p. 3000°C; sp. gr. 5.96 (20°C); valence 2, 3, 4 or 5. Discovered by Sefstrom in 1830; isolated by Roscoe in 1869. Though relatively rare, vanadium is found in a variety of minerals; prominent among these are *vanadinite* ($3PO_3(VO_4)_2.PbCl_2$) and *patronite* (possibly VS_4) occurring in Peru. Vanadium is obtained by reduction of the chloride in hydrogen, forming a gray and very infusible metal. The vanadates are employed in the preparation of aniline black and for coloring glass. Most of it is produced as ferro-vanadium and used in the manufacture of steel alloys, greatly increasing toughness, elasticity and tensile strength. V_2O_5 masses are used in the contact process for manufacture of sulfuric acid.

Wolfram (see Tungsten).

Xenon (Gr. *xenon*, stranger), Xe; at. wt. 131.3; at. no. 54; m.p. −112°C; b.p. −107.1°C; density 5.85 g/l, sp. gr. liquid 3.52 (−109°C); valence 0. Discovered by Ramsay and Travers in 1898 in the residue left on evaporating liquid air. It is the rarest and heaviest of the gases of the argon family from the atmosphere, in which it is present to the extent of about one part in twenty million. It is inert and forms no compounds with other elements. Vacuum tubes containing it show a beautiful blue glow.

Ytterbium (Ytterby, village in Sweden), Yb; at. wt. 173.04; at. no. 70; m.p. 1800°C; b.p. . . . . ; sp. gr. . . . . . . ; valence 3. Separated by Marignac in 1878. In 1907 Urbain and in 1908 von Welsbach described a process by which this earth containing the metal, could be resolved into earths of two other metals—neo-ytterbium, or simply ytterbium, and lutetium. These elements occur in nearly all minerals which contain yttrium, but in very small amounts The best sources are probably *gadolinite*, *xenotime*, *polycrase* and *blomstrandine*. The oxide, chloride and sulfate have been prepared.

Yttrium (Ytterby, village in Sweden), Y; at. wt. 88.92; at. no. 39; m.p. 1490°C; b.p. 2500°C; sp. gr. 5.51; valence 3. The rare earth yttria, which contained a new element, was discovered by Gadolin in 1794; in 1843 Mosander showed that yttria could be resolved into the earths of three other elements, the name yttria being reserved for the most basic one, the others being named erbia and terbia. Yttrium occurs in nearly all of the rare earths minerals. Wöhler obtained the free element by reduction of the chloride with potassium; it has also been obtained by the electrolysis of a mixture of the chloride and sodium chloride. The metal forms small scales with a metallic luster and an iron-gray color; it is readily oxidized in air and is converted to the hydroxide by boiling water. Y_2O_3 is white; rapidly attacked by most acids to give colorless solutions.

Zinc (G. *Zink*), Zn; at. wt. 65.38; at. no. 30; m.p. 419.5°C; b.p. 907°C; sp. gr. 7.14 (20°C); valence 2. Its ores were used for making brass for centuries before it was recognized as a separate metal in 1746 by Marggraf, who obtained it by heating calamine with charcoal. The principal ores are *sphalerite* or *blende* (sulfide), *smithsonite* (carbonate) and *calamine* (silicate). The old method of heating the roasted ore with carbon in a retort is still used, being replaced to some extent by the electrolytic process. Zinc is a bluish-white metal, brittle at ordinary temperatures but malleable at 100°C, a fair conductor of electricity; it burns in air at high red heat with evolution of white clouds of the oxide; it is used to form numerous alloys with other metals, as brass with copper. Galvanizing is coating other metals, especially iron, with zinc to prevent corrosion; the coating is sometimes applied by dipping in molten zinc. This is the most important use of the metal; die casting and brass making use large quantities. Zinc is used as the negative electrode in various types of electric batteries. Compounds are widely used in paints, the oxide being an important white pigment; its compounds have antiseptic properties and are used in medicine. Nearly a century ago Frankland showed the use of zinc in preparing organic compounds.

Zirconium (Arabic *zargun*, gold color), Zr; at. wt. 91.22; at. no. 40; m.p. 1857°C; b.p. above 2900°C; sp. gr. 6.4 (20°C); valence 4. Discovered in *zircon* by Klaproth in 1789; isolated by Berzelius in 1824. Rather widely diffused in igneous rocks, zirconium usually occurs in the silicate, $ZrSiO_4$. The element is in the titanium family, its oxide being either base or acid forming. Prepared from the tetrachloride by heating with sodium in a bomb, the metal can be pressed into rods, drawn into wire, or burnished to a bright surface. A number of alloys have been made. Ferro-zirconium, made by aluminum reduction in an electric furnace, is used for desulfurizing and deoxidizing steel. Zircon, the silicate, is sometimes a gem. The oxide has been used in gas mantles, in paints as an opacifier, in lacquers, in insulators and as an abrasive.

****Einsteinium** (Albert Einstein), E; at no. 99. Was produced in the thermonuclear explosion staged by the Los Alamos Scientific Laboratory in 1952 by A. Ghiorso and coworkers. The existence of a relatively long-lived isomeric form of E^{254} produced by neutron bombardment makes it possible to isolate this element in weighable amounts.

****Fermium** (Enrico Fermi), Fm; at. no. 100. Was discovered in the thermonuclear explosion during the same series of experiments that resulted in the discovery of Einsteinium. Since Fm^{255} is the longest-lived fermium isotope known it seems improbable that this element can ever be obtained in weighable amount.

****Mendelevium** (D. Mendeleev), Mv; at. no. 101. Was discovered by Ghiorso, Harvey, Choppin, Thompson, and Seaborg in 1955 as a result of the irradiation of extremely small amounts of E^{253} with helium ions in the Berkeley 60 inch cyclotron. The isotope produced was Mv^{256} which has a half-life of about 0.5 hours. Since there appear to be no long-lived isotopes it seems improbable that this element will ever be isolated in weighable amount.

Nobelium (A. Nobel), No; at. no. 102. Was discovered by P. R. Fields and coworkers at Argonne National Laboratory, British Atomic Energy Est., Harwell, England, and Nobel Institute at Stockholm, Sweden, in 1957, as the result of irradiation of specially prepared targets of Cf with carbon C^{13} ions in the Nobel Institute cyclotron at Stockholm. The isotope produced was No^{253} which has a half-life of about ten minutes.

** For further description see following section "Transuranium Elements."

TRANSURANIUM ELEMENTS

The available evidence leads to the natural conclusion that the heaviest elements of the *periodic system* of atomic numbers 89 (actinium) through 103 are so chemically similar to another group of elements, the *rare earths* or lanthanide series (atomic numbers 57–71) that their electronic structures must also be similar, and they have been given the name *actinides*. An inner electron shell, consisting of fourteen 5f electrons, is filled in progressing across the series. Those elements with atomic number greater than 92, uranium, have half-lives too short to have existed since their original creation. They were discovered and produced by nuclear reactions and synthesis and are called the *transuranium* elements. The presently known (1955) transuranium elements have the following names and symbols: 93, neptunium (Np); 94, plutonium (Pu); 95, americium (Am); 96, curium (Cm); 97, berkelium (Bk); 98, californium (Cf); 99, einsteinium (E); 100, fermium (Fm); and 101, mendelevium (Mv).

Chemically the transuranium elements are very similar, although the observed differences are those expected and anticipated from their unique position in the periodic system as part of a second rare-earth series. All have trivalent ions, which form inorganic complex ions and organic chelates. Also in common are acid-insoluble trifluorides and oxalates, soluble sulfates, nitrates, chlorides, and perchlorates. Neptunium, plutonium, and americium have higher oxidation states in aqueous solution (similar to uranium), but the relative stability of these states to the common trivalent ion becomes progressively less as one proceeds to the higher atomic numbers. This is a direct consequence, indeed an identifying feature, of the actinide role as a second rare-earth type transition series.

One of the most important methods for study and elucidation of chemical behavior of the actinide elements has been ion-exchange chromatography. Adsorption on and elution from ion-exchange columns has made possible the identification and separation of trace quantities of all of the actinides and in particular the transuranium elements. The behavior of each actinide and transuranium element in this respect is very similar to its analogous rare-earth element. This has made it possible to detect as little as one or two atoms when this small a number has been made in some of the transmutation experiments.

Neptunium (Np, atomic number 93, after the planet Neptune). Neptunium was the first of the synthetic transuranium elements to be discovered; the isotope Np^{239} was produced by McMillan and Abelson in 1940 at Berkeley, California, as the result of the bombardment of uranium with cyclotron-produced neutrons. The isotope Np^{237} (half-life of 2.2×10^6 years) is currently obtained in gram quantities as a by-product from nuclear reactors in the production of plutonium. Trace quantities of the element are actually found in nature due to transmutation reactions in uranium ores produced by the neutrons which are present.

Neptunium metal has a silvery appearance, is chemically reactive, melts at 640° C and exists in at least three structural modifications: α-neptunium, orthorhombic, density = 20.45 g/cm^3; β-neptunium (above 278° C), tetragonal, density (313° C) = 19.36 g/cm^3; γ-neptunium (above 500° C) cubic, density (600° C) = 18.0 g/cm^3.

Neptunium gives rise to four ionic oxidation states in solution: Np^{+3} (pale purple), analogous to the rare earth ion Pm^{+3}, Np^{+4} (yellow green), NpO_2^+ (green blue), and NpO_2^{++} (pale pink). These latter oxygenated species are in contrast to the rare earths which exhibit only simple ions of the (II), (III), and (IV) oxidation states in aqueous solution. The element forms tri- and tetrahalides such as NpF_3, NpF_4, $NpCl_4$, $NpBr_3$, NpI_3, and oxides of various compositions such as are found in the uranium-oxygen system, including Np_3O_8 and NpO_2.

Plutonium (Pu, atomic number 94, after the planet Pluto). Plutonium was the second transuranium element to be discovered; the isotope Pu^{238} was produced in 1940 by Seaborg, McMillan, Kennedy, and Wahl at Berkeley, California, by deuteron bombardment of uranium in the 60-inch cyclotron. By far of greatest importance is the isotope Pu^{239} (half-life of 24,400 years), produced in extensive quantities in nuclear reactors from natural uranium:

$$U^{238}(n,\gamma)U^{239} \xrightarrow{\beta^-} Np^{239} \xrightarrow{\beta^-} Pu^{239}.$$

Plutonium has assumed the position of dominant importance among the transuranium elements because of its successful use as an explosive ingredient in nuclear weapons and the place which it holds as a key material in the development of industrial utilization of nuclear energy, one pound being equivalent to about 10,000,000 kilowatt hours of heat energy. Its importance depends on the nuclear property of being readily fissionable with neutrons and its availability in quantity.

Plutonium also exists in trace quantities in naturally occurring uranium ores. It is formed in much the same manner as neptunium, by irradiation of natural uranium with the neutrons which are present.

Plutonium metal can be prepared, in common with neptunium and uranium, by reduction of the trifluoride with alkaline-earth metals. The metal has a silvery appearance, is chemically reactive, and melts at 635° C. It exhibits at least five crystalline modifications: α-plutonium, orthorhombic, below 117° C; β,γ-plutonium, of unknown crystalline forms, 117°–300° C; δ-plutonium, face-centered cubic, 300°–475° C; and ϵ-plutonium, body-centered cubic, 475° C up to the melting point.

Plutonium also exhibits four ionic valence states in aqueous solutions: Pu^{+3} (blue lavender), Pu^{+4} (yellow brown), PuO_2^+ (presumably pink), and PuO_2^{+2} (pink orange). The ion PuO_2^+ is unstable in aqueous solutions, disproportionating into Pu^{+4} and PuO_2^{+2}; the Pu^{+4} thus formed, however, oxidizes the

PuO_2^+ into PuO_2^{+2}, itself being reduced to Pu^{+3}, giving finally Pu^{+3} and PuO_2^{+2}.

Plutonium forms binary compounds with oxygen: PuO, PuO_2, and intermediate oxides of variable composition; with the halides: PuF_3, PuF_4, $PuCl_3$, $PuBr_3$, PuI_3; with carbon, nitrogen and silicon: PuC, PuN, $PuSi_2$; in addition, oxyhalides are well known: PuOCl, PuOBr, PuOI.

Because of the high rate of emission of alpha particles, and the physiological fact that the element is specifically absorbed by bone marrow, plutonium, as well as all of the other transuranium elements except neptunium, are radiological poisons and must be handled with special equipment and precautions.

Americium (Am, atomic number 95, after the Americas). Americium was the fourth transuranium element to be discovered; the isotope Am^{241} was identified by Seaborg, James, Morgan and Ghiorso late in 1944 at the wartime Metallurgical Laboratory (now the Argonne National Laboratory) of the University of Chicago as the result of successive neutron capture reactions by plutonium isotopes in a nuclear reactor:

$$Pu^{239}(n,\gamma)Pu^{240}(n,\gamma)Pu^{241} \xrightarrow{\beta^-} Am^{241}.$$

Americium is produced in gram quantities. Since the isotope Am^{241} can be prepared in relatively pure form by extraction as a decay product over a period of years from strongly neutron-bombarded plutonium containing Pu^{241}, this isotope is used for much of the chemical investigation of this element. Better suited is the isotope Am^{243} due to its longer half-life (8.8×10^3 years as compared to 470 years for Am^{241}). A mixture of the isotopes Am^{241}, Am^{242}, and Am^{243} can be prepared by intense neutron irradiation of Am^{241} according to the reactions $Am^{241}(n,\gamma)Am^{242}(n,\gamma)Am^{243}$. Nearly isotopically pure Am^{243} can be prepared by a sequence of neutron bombardments and chemical separations as follows. Neutron-bombardment of Am^{241} yields Pu^{242} by the reactions $Am^{241}(n,\gamma)Am^{242} \xrightarrow{EC} Pu^{242}$; after chemical separation the Pu^{242} can be transformed to Am^{243} via the reactions $Pu^{242}(n,\gamma)Pu^{243} \xrightarrow{\beta^-} Am^{243}$, and the Am^{243} can be chemically separated. Fairly pure Pu^{242} can be prepared more simply by very intense neutron irradiation of Pu^{239} as the result of successive neutron-capture reactions.

Americium can be obtained as a silvery white reactive metal by reduction of americium trifluoride with barium vapor at 1000°–1200° C. It appears to be more malleable than uranium or neptunium and tarnishes slowly in dry air at room temperature. The density is 11.7 g/cm^3 with melting point somewhat higher than 850° C.

The element exists in three oxidation states in aqueous solution: Am^{+3} (light salmon), AmO_2^+ (color unknown), and AmO_2^{+2} (light tan). The trivalent state is highly stable and difficult to oxidize. AmO_2^+, like plutonium, is unstable with respect to disproportionation into Am^{+3} and AmO_2^{+2}. The ion Am^{+4} is so unstable in solution that it has not yet been detected, although tetravalent solid compounds are well known. There is some evidence that Am^{+2} has been prepared in tracer experiments at very low concentrations; this would be very similar to the analogous lanthanide, europium, which can be reduced to the divalent state.

Americium dioxide, AmO_2, is the important oxide; Am_2O_3 and, as with previous actinide elements, oxides of variable composition between $AmO_{1.5}$ and AmO_2 are known. The halides AmF_3, AmF_4, $AmCl_3$, $AmBr_3$, and AmI_3 have also been prepared.

Curium (Cm, atomic number 96, after Pierre and Marie Curie). Although curium comes after americium in the periodic system, it was actually known before americium and was the third transuranium element to be discovered. It was identified by Seaborg, James, and Ghiorso in the summer of 1944 at the wartime Metallurgical Laboratory in Chicago as a result of helium-ion bombardment of Pu^{239} in the Berkeley, California, 60-inch cyclotron. It is of special interest because it is in this element that the first half of the transition series of actinide elements is completed.

The isotope Cm^{242} (half-life 162.5 days) produced from Am^{241} by the reactions $Am^{241}(n,\gamma)Am^{242} \xrightarrow{\beta^-} Cm^{242}$ has been used for much work with macroscopic quantities, although this is difficult due to the extremely high specific alpha activity. An excellent isotope for the investigation of curium in weighable amounts is Cm^{244} because it has a half-life of 19 years and can be prepared in fairly pure form by a sequence of neutron bombardments and chemical separations as follows. The neutron-bombardment of Am^{241} yields Pu^{242} by the reactions $Am^{241}(n,\gamma)Am^{242} \xrightarrow{EC} Pu^{242}$; after chemical separation the Pu^{242} can be transformed to Am^{243} via the reactions $Pu^{242}(n,\gamma)Pu^{243} \xrightarrow{\beta^-} Am^{243}$. Fairly pure Pu^{242} can be prepared more simply by very intense neutron irradiation of Pu^{239} as the result of successive neutron-capture reactions. The Am^{243} can be chemically separated and finally transmuted to Cm^{244} through neutron bombardment by the reactions $Am^{243}(n,\gamma)Am^{244} \xrightarrow{\beta^-} Cm^{244}$. Further neutron bombardment of Cm^{244} produces higher-mass isotopes of longer half-life which are even better for use in the investigation of curium.

Curium metal resembles the other actinide metals quite closely. Also, in common with other metals, it can be prepared by heating curium trifluoride with barium vapor at 1275° C.

The only oxidation state in aqueous solutions which has been definitely identified is Cm^{+3}, although a solid, black CmO_2 has been prepared. Cm_2O_3 and CmF_3, both white compounds, have also been characterized. The general trend of decreasing stability of higher oxidation states with increasing atomic number would indicate that oxidation states of curium higher than curium(III) will probably not be stable in aqueous solutions. It has further been demonstrated that curium(III) cannot be reduced in aqueous solutions.

It is interesting to note that the experimentally determined magnetic susceptibility of CmF_3 is in good agreement with the value expected for the electronic structure $5f^7$ in curium(III), assuming a Russell-Saunders coupling scheme.

Berkelium (Bk, atomic number 97, after Berkeley, California). Berkelium, the eighth member of the actinide transition series, was discovered in December, 1949 by Thompson, Ghiorso, and Seaborg and was the fifth transuranium element synthesized. It was produced by cyclotron bombardment of Am^{241} with helium ions at Berkeley, California.

The chemical properties of berkelium have been studied entirely to date through the use of tracer amounts. These studies have demonstrated that berkelium exists in aqueous solutions in two oxidation states, berkelium(III) and berkelium(IV). The chemistry and solubility of compounds appears to closely follow the other transuranium elements.

The existence of Bk^{249} with a half-life of about 300 days makes it feasible to isolate berkelium in weighable amounts so that its properties can be investigated with macroscopic quantities. This isotope can be prepared by the intense neutron bombardment of Cm^{244} as the result of the capture of successive neutrons by the reactions

$$Cm^{244}(n,\gamma)Cm^{245}(n,\gamma)Cm^{246}(n,\gamma)Cm^{247}(n,\gamma)Cm^{248}(n,\gamma)Cm^{249} \xrightarrow{\beta^-} Bk^{249}.$$

Californium (Cf, atomic number 98, after the state and University of California). Californium, the sixth transuranium element to be discovered, was produced by Thompson, Street, Ghiorso, and Seaborg in January, 1950 by helium-ion bombardment of microgram quantities of Cm^{242} in the Berkeley 60-inch cyclotron. Like berkelium, its chemical properties have been studied solely with tracer amounts. Californium(III) is the only ion stable in aqueous solutions, all attempts to reduce or oxidize californium(III) having failed. The existence of the isotopes Cf^{249}, Cf^{250}, Cf^{251}, and Cf^{252} makes it feasible to isolate californium in weighable amounts so that its properties can be investigated with macroscopic quantities. The isotope Cf^{249} results from the beta decay of Bk^{249} while the heavier isotopes are produced by intense neutron irradiation by the reactions $Bk^{249}(n,\gamma)Bk^{250} \xrightarrow{\beta^-} Cf^{250}$ and $Cf^{249}(n,\gamma)Cf^{250}$ followed by $Cf^{250}(n,\gamma)Cf^{251}(n,\gamma)Cf^{252}$.

Einsteinium (E, atomic number 99, after Albert Einstein). Einsteinium, the seventh transuranium element to be discovered, was identified by Ghiorso *et al.* in December, 1952 in the debris from a thermonuclear explosion in work involving the University of California Radiation Laboratory, the Argonne

National Laboratory, and the Los Alamos Scientific Laboratory. The isotope produced was the 20-day E^{253}, originating from beta decay of U^{253} and daughters. Its chemical properties have been studied solely with tracer amounts and indicate that the (III) oxidation state may be the only one which exists in aqueous solution. Existence of a relatively long-lived isomeric form of E^{254} makes it possible to isolate this element in weighable amounts. The isotope E^{253} and heavier isotopes can be produced by intense neutron irradiation of lower elements such as plutonium, by a process of successive neutron capture interspersed with beta decays until these mass numbers and atomic numbers are reached.

Fermium (Fm, atomic number 100, after Enrico Fermi). Fermium, the eighth transuranium element to be discovered, was identified by Ghiorso *et al.* early in 1953 in the debris from a thermonuclear explosion in work involving the University of California Radiation Laboratory, the Argonne National Laboratory, and the Los Alamos Scientific Laboratory. The isotope produced was the 16-hour Fm^{255}, originating from the beta decay of U^{255} and daughters. Since this is the longest-lived presently known fermium isotope it seems unlikely that this element can be isolated in weighable amount. Its chemical properties have been studied solely with tracer amounts and in normal aqueous media only the (III) oxidation state appears to exist. The isotope Fm^{254} and heavier isotopes can be produced by intense neutron irradiation of lower elements, such as plutonium, by a process of successive neutron capture interspersed with beta decays until these mass numbers and atomic numbers are reached.

Mendelevium (Mv, atomic number 101, after Dmitri Mendeleev). Mendelevium, the ninth transuranium element to be discovered, was first identified by Ghiorso, Harvey, Choppin, Thompson, and Seaborg in early 1955 as a result of the bombardment of the isotope E^{253} with helium ions in the Berkeley 60-inch cyclotron. The isotope produced was presumably Mv^{256} which apparently decays by electron capture to Fm^{256}, which in turn decays predominantly by spontaneous fission with a half-life of about 3 hours. This first identification was notable in that only of the order of one to three atoms per experiment were produced. The extreme sensitivity for detection depended on the fact that its chemical properties could be accurately predicted as eka-thulium and there was a high sensitivity for detection because of the spontaneous fission decay. The chemical properties have been investigated solely by the tracer technique and seem to indicate that the predominant oxidation state in aqueous solution is the (III) state. There seem to be no isotopes of sufficiently long half-life to make it possible to isolate this element in weighable quantity.

EXPLANATION

The atomic number for each element appears in the upper left corner and the atomic weight in the right corner of each box.

Following the name and symbol there are given the mass numbers of the isotopes which have been established as certain or probable (Classes A and B, Seaborg and Perlman, 1948).

The stable elements and stable isotopes are in bold face type.

The radioactive elements and isotopes are in Roman type.

m following the mass number denotes a metastable isomer.

n following the mass number denotes a naturally occurring radioactive isotope.

TABLE OF THE ISOTOPES

Compiled by John R. Bradford

The isotopes are listed by atomic number Z (number of protons), and by mass number A (number of protons and neutrons). The percentage of abundance of the nuclide in the naturally occurring mixtur of isotopes is given for the stable isotopes and for some long-live natural radioisotopes. The relative natural isotope abundance value are expressed as percentage of total number of atoms.

The atomic mass values are given for neutral atoms on the physica scale. The O^{16} nuclide is arbitrarily assigned the mass of 16.000000

Data included up to February 1, 1953.

Half-life values are given in terms of seconds s, minutes m, hours h days d, and years y.

The modes of decay and types of radiation are given using th symbols:

α alpha particle	n neutron
β^- beta particle	p proton
β^+ positron	↓IT isomeric transition
γ gamma ray	f fission product (thermal neutron fission of U^{235})
e^- internal electron conversion	NR natural radioactivity
K orbital electron capture	

All energies of radiation are given in Mev (Million electron volts) The series name for natural occurring radioisotopes is given in th atomic mass column.

Z	Isotope	% Nat. Abund.	Atomic Mass (A)	Half Life	Mode of Decay Radiation	— Energies in MEV

Packing fraction is the difference between the actual mass of the isotope and the nearest whole number divided by the mass number. Thus the packing fraction is equal to $(M - A)/A$ where M is the actual mass and A is the mass number. For example, one of the chlorine isotopes has a mass of 32.9860. The packing fraction for this isotope is $\frac{32.9860 - 33.0000}{33.0000} = -0.00042$. Packing fractions are usually expressed as parts per 10,000 and so the packing fraction for this isotope of chlorine is written as -4.2. Since oxygen is taken as the standard, elements with positive packing fractions are less stable than oxygen, those with negative packing fractions are more stable. It is positive for nuclides with mass number 16 or greater than 180 and negative for most others.

THERMAL NEUTRON CROSS SECTIONS

Compiled by John R. Bradford

The table of Thermal Neutron Cross Sections is taken from data published by the Neutron Cross Section Advisory Group of the Atomic Energy Commission.

All values given for an element refer to the natural mixture of isotopes, that is, they are atomic cross sections, while those given for specific isotopes are isotopic cross sections. All cross sections, unless marked mb (millibarns) are in barns (10^{-24} cm^2).

The reaction cross sections listed are those for a neutron velocity of 2200 meters per second. The reaction cross sections refer to all cases in which the neutron is not re-emitted, that is, to (n,γ), (n,p), and (n,α) reactions. Practically all the reaction cross sections are for (n,γ) reactions and the few that are not are so marked. The absorption cross sections, σ_{abs}, are the particular reaction cross sections that are measured by observing the reaction itself in which the neutron is absorbed. The activation cross sections, σ_{act}, are those determined from the radioactivity of the product nucleus, usually the result of an (n,γ) reaction, and in a few cases, which are specially marked, by (n,p) or (n,α) reactions. The activation cross sections always refer to particular isotopes and hence are isotopic cross sections; for mono-isotopic elements they are atomic cross sections as well. For a few cases in which the 2200 m/s value could not be determined, the cross sections are still included but are marked with an asterisk* indicating "pile neutrons."

The scattering cross sections are usually constant with energy in the thermal region, except for crystal effects, and are hence not quoted for 2200 m/s. The average scattering cross section, $\bar{\sigma}_s$, is that averaged over the Maxwell distribution and will depend on the crystalline form of the sample and even upon the size of the crystal grain, but it is listed here because of utility in certain practical applications.

EXPLANATION OF TABLE

The table presents data for about four thousand compounds. The first section includes inorganic compounds and the metallic salts of organic acids, and the second metal-organic compounds.

It is intended that the substances listed include the more important definite compounds for which data are available. Some are listed because of their theoretical importance, even when no constants can be given.

Nomenclature and Arrangement.—The names used for the compounds conform to the best current usage insofar as this could be ascertained, the Rules for Naming Inorganic Compounds adopted January 28–29, 1938, by the Committee for the Reform of Inorganic Chemical Nomenclature of the International Union for Chemistry and the names used in Chemical Abstracts indexes being used as a guide to some extent. The compounds are listed under the names of the elements in alphabetical order, except that acids and a few other compounds (e.g. hydrazine, hydroxylamine, and sulfuryl, thionyl and uranyl compounds) have their own headings. Ferrous and ferric compounds are entered under iron, stannous and stannic, under tin, cuprous and cupric, under copper and aurous and auric, under gold. "Acid salts" (including hydrosulfides) and many "basic salts" are placed immediately after the normal salts. Names like bicarbonate and bisulfate have not been used for acid salts, (the hydrogen usually being named instead), but names like antimony oxychloride and uranyl nitrate have been used for some basic salts. Prefixes such as di-, tri-, ortho-, meta-, pyro-, hypo-, and per- are not alphabetized. Iso-, however, and prefixes like chloro- in chloroplatinic acid are alphabetized. For the naming of binary compounds of nonmetallic elements the order of decreasing electropositivity given in the Report of the German Commission for Nomenclature (Meyer, *Helvetica Chimica Acta* 20, 159–75 (1937)) has been followed: Sb, As, B, Si, C, P, Te, Se, S, I, Br, Cl, N, O, F, except in the case of nitrogen chlorides, nitrogen iodides, etc. Binary compounds of hydrogen (except ammonia and water) are listed under hydrogen arsenide (instead of arsine), hydrogen chloride, hydrogen phosphide (instead of phosphine), hydrogen sulfide and like names. Most ammino and related compounds are grouped under headings like **Cobalt complexes** following the other compounds of the element in question, while complexes that have reasonably well-established names like chloroplatinate, cyanoplatinite, fluoborate, ferrocyanide and ferricyanide are listed under these names just like simpler salts. In a few less common names for anions, particularly of elements having more than two oxidation states, stock names with Roman numerals to indicate oxidation state have been introduced, for example, ferrate (III) (ferrite), chloroosmate (III) (chloroosmite), nitrocobaltate (III) (cobaltinitrite). Double salts (including alums) are entered only once: (1) those with two cations are given with the more electropositive cation first in the order of the electromotive force series: Li, Rb, K, Na, NH_4, Sr, Ba, Ca, Mg, Al, U, Mn, Zn, Cr, Ga, Fe^{++}, Cd, In, Tl, Co, Ni, Sn, Pb, Fe^{+++}, Sb, Bi, As, Cu, Ag, Hg, Pd, Pt, Au (e.g. sodium aluminum sulfate, ammonium magnesium phosphate); (2) those with two anions are given with the anions in alphabetical order (e.g., strontium chloride fluoride). The finding of compounds known also under names about as common as those listed is facilitated by a **Synonym Index,** which precedes the table. Organic names conform to those used in the Table of Physical Constants of Organic Compounds.

Molecular weights have been computed to the nearest hundredth, based on the **International Atomic Weights of 1949.**

The **Crystalline form and color** are stated in easily interpreted abbreviations. Other important characteristics are often added. **Indices of refraction** are given in the same column. For crystals with two or three indices, they are invariably given in the order ω, ϵ or α, β, γ. All indices are for sodium light ($\lambda = .5893\mu$) unless otherwise stated. The temperature is assumed to be normal room temperature unless otherwise indicated by a superior figure following the index. 1.536^{25} (Li) would be interpreted as giving the value for the index of refraction of a substance for the red line of lithium at 25°C.

Specific gravity at 20°C, referred to water at 4°C, is normally given. Other temperatures are indicated by superior and inferior figures. For example: 2.64^{25}_{15} indicates a specific gravity of 2.64 at 25°C, referred to water at 15°C. It should be noted that values of specific gravity referred to water at 4°C are numerically equivalent to density in grams per milliliter. The **density of gases** is given in grams per liter, indicated g/l, at 0°C and 1 atm.

Melting and boiling points are given in °C. The boiling point is stated at normal atmospheric pressure (760 mm of Hg) unless otherwise indicated by a superscript which is to be interpreted as the pressure in mm of Hg under which the compound boils at the temperature given. For example: 250^{732} indicates a boiling point of 250°C under a pressure of 732 mm Hg; $426^{2\ \mathrm{atm.}}$ indicates a boiling point of 426°C under a pressure of 2 atmospheres. Decomposition on heating is indicated by the abbreviation d. in melting or boiling point column. If decomposition occurs without change of state, the form d. 120 is used indicating the occurrence of decomposition at 120°C. The form 120 d. would indicate a melting or boiling point of 120°C with decomposition. Loss of water of crystallization or oxygen is indicated by the form $-2H_2O$ or $-O$. The figures $-5H_2O$, 350 indicate the loss of five molecules of water of crystallization at 350°C.

Solubilities are stated for normal room temperatures, 20°C, unless otherwise indicated by a superior figure. 6.8^{25} indicates a solubility of 6.8 grams of substance in 100 ml of the solvent at 25°C. The term insoluble (i.) must be usually understood to mean that a negligible quantity of the compound dissolves. A large proportion of salts commonly regarded as insoluble really dissolve to a very slight extent. The form s.d. indicates solubility with more or less decomposition. The abbreviation d. alone in the solubility column indicates that decomposition is the primary action occurring. Solubility in acids and alkalies is usually understood to be accompanied by decomposition.

Acetylacetonate	2,4-pentanedione deriv.
Alabandite	Manganese sulfide (ous)
Alamosite	Lead *meta*silicate
Albite	Sodium aluminosilicate
Altaite	Lead telluride
Alum, ammonium	Ammonium aluminum sulfate
Alum, cesium	Cesium aluminum sulfate
Alum, ammonium chrome	Ammonium chromium sulfate
Alum, ammonium gallium	Ammonium gallium sulfate
Alum, ammonium vanadium	Ammonium vanadium sulfate
Alum, iron ammonium	Ammonium iron sulfate
Alum, iron potassium	Potassium iron sulfate
Alum, manganese potassium	Potassium manganese sulfate
Alum, potassium	Potassium aluminum sulfate
Alum, potassium chrome	Potassium chromium sulfate
Alum, rubidium	Rubidium aluminum sulfate
Alum, sodium	Sodium aluminum sulfate
Alum, thallium	Aluminum thallium sulfate
Alumina	Aluminum oxide
Alunogenite	Aluminum sulfate
Amidosulfonic acid	Sulfamic acid
Amidosulfuric acid	Sulfamic acid
Aminosulfonic acid	Sulfamic acid
Anatase	Titanium oxide, di-
Anglesite	Lead sulfate
Anhydrite	Calcium sulfate
Anhydrite, soluble	Calcium sulfate
Anorthite	Calcium aluminosilicate
Antimony hydride	Hydrogen antimonide
Antimony thioglycolamide	Antimony α mercaptoacetamide
Aquopentamminecobalt (III) chloride	under Cobalt complexes
Aragonite	Calcium carbonate
Arcanite	Potassium sulfate
Argentic, argentous	under Silver
Argentite	Silver sulfide
Arsenic hydride	Hydrogen arsenide
Arsenic red	Arsenic sulfide, di-
Arsenoferrite	Iron arsonide, di-
Arsenolite	Arsenic oxide, tri-
Arsine	Hydrogen arsenide
Artinite	Magnesium carbonate, basic
Ascharite	Magnesium *pyro*borate
Atacamite	Copper oxychloride (ic)
Auricyanide	Cyanoaurate (III)
Auric salts	under Gold
Auroauric	under Gold
Aurocyanide	Cyanoaurate (I)
Aurous salts	under Gold
Avogadrite	Potassium fluoborate
Azoimide	Hydrazoic acid
Azurite	Copper carbonate, basic (ic)
Baddeleyite	Zirconium oxide, di-
Baking soda	Sodium carbonate, hydrogen
Barite	Barium sulfate
Baryta	Barium oxide
Barytes	Barium sulfate
Bayerite	Aluminum oxide
Benzylate	Benzyloxide
Berlin green	Iron ferricyanide (ic)
Bertrandite	Beryllium *ortho*silicate
Beryl	Beryllium aluminum silicate
Bicarbonate	Carbonate, hydrogen
Bieberite	Cobalt sulfate (ous)
Binoxalate	Oxalate, hydrogen
Bischofite	Magnesium chloride
Bismite	Bismuth oxide, tri-
Bismuth oxynitrate	Bismuth nitrate, basic
Bismuth subnitrate	Bismuth nitrate, basic
Bismuthic acid, meta-	Bismuth oxide, pent-
Bismuthine	Hydroxide bismuthide
Bismuthinite	Bismuth sulfide, tri-
Bismuthyl	Bismuth oxy-
Bisulfate, -ite	Sulfate, -ite, hydrogen
Bisulfide	Disulfide
Bleaching powder, chlorinated lime	Calcium chloride hypochlorite
Bloedite	Sodium magnesium sulfate
Blue verdigris	Copper acetate, basic
Blue vitriol	Copper sulfate (ic)
Bobierrite	Magnesium *ortho*phosphate
Boehmite	Aluminum hydroxide
Boracic acid	Boric acid
Borax	Sodium *tetra*borate
Boric anhydride	Boron oxide
Borobutane	Boron hydride
Boroethane	Boron hydride
Borofluoric acid	Fluoboric acid
Borofluoride	Fluoborate
Boussingaultite	Ammonium magnesium sulfate
Breithauptite	Nickel antimonide
Bromellite	Beryllium oxide
Bromoazide	Bromine azide
Bromyrite	Silver bromide
Brookite	Titanium oxide, di-

Carbon oxychloride	Carbonyl chloride
Carbon oxysulfide	Carbonyl sulfide
Carnallite	Potassium magnesium chloride
Caro's acid	Sulfuric acid, peroxymono-
Cassel yellow	Lead oxychloride
Cassiopeum	Lutetium
Cassiterite	Tin oxide mon-
Celestite	Strontium sulfate
Cerargyrite	Silver chloride
Cerussite	Lead carbonate
Cervantite	Antimony oxide, tetra-
Chalcanthite	Copper sulfate (ic)
Chalcocite	Copper sulfide (ous)
Chamber crystals	Nitrosylsulfuric acid
Chessylite	Copper carbonate, basic (ic)
Chloride of Millon's base	Mercury chloride (ic), aquobasic ammonobasic
Chlorinated lime	Calcium chloride hypochlorite
cis-Chloroaquotetrammine cobalt (III) chloride	under Cobalt complexes
Chlor(o)azide	Chlorine azide
Chlorocalcite	Potassium calcium chloride
Chloromanganokalite	Potassium manganese chloride (ous)
Chloropentammine chromium (III) chloride	under Chromium complexes
Chloropentamminecobalt (III) chloride	under Cobalt complexes
Chrome red	Lead chromate, basic
Chrome yellow	Lead chromate
Chromic anhydride	Chromium oxide, tri-
Chromyl	Chromium oxy-
Chrysoberyl	Beryllium aluminate
Cinnabar	Mercury sulfide (ic) (α)
Claudetite	Arsenic oxide, tri-
Clausthalite	Lead selenide
Clinoenstatite	Magnesium silicate
Cobalticyanic acid	Cyanocobaltic (III) acid
Cobalticyanide	Cyanocobaltate (III)
Cobaltinitrite	Nitrocobaltate (III)
Cobaltite	Cobalt arsenic sulfide
Columbic acid	Niobium oxide, pent-
Columbium	Niobium
Common salt	Sodium chloride
Coquimbite	Iron sulfate (ic)
Corrosive sublimate	Mercury chloride
Corundum	Aluminum oxide, α-
Cotunnite	Lead chloride
Covellite	Copper sulfide (ic)
Cream of tartar, soluble	Potassium borotartrate
Cristobalite	Silicon oxide, di-
Crocoite	Lead chromate
Cryolite	Sodium fluoaluminate
Cryolithionite	Lithium sodium fluoaluminate
Cryptohalite	Ammonium fluosilicate
Crystal carbonate	Sodium carbonate
Crythrosiderite	Iron chloride (ic)
Cuprammonium	under Copper complexes
Cupric	under Copper
Cuprite	Copper oxide (ous)
Cuprous	under Copper
Cyanoauric acid	Gold cyanide (ic)
Cyanoferrates (II)	Ferrocyanides
Cyanoferrates (III)	Ferricyanides
Cyanoferric (II) acid	Ferrocyanic acid
Cyanoferric (III) acid	Ferricyanic acid
Decaborane	Boron hydride
Decaborate	Ammonium pentaborate
Deuterioammonia, tri-	Ammonia-d_3
Diamminecopper (II) acetate	under Copper complexes
Diamminepalladium (II) hydroxide	under Palladium complexes
Diaquotetramminenickel (II) nitrate	under Nickel complexes
Diaspore	Aluminum hydroxide
Diborane	Boron hydride
Dichlorodiamminepalladium (II) *trans.*	under Palladium complexes
Digallane	Gallium hydride
Digermane	Germanium hydride
Dihydropentaborane	Borane hydride
Dihydrotetraborane	Boron hydride
Diopside	Calcium magnesium silicate
Disilane	Silicon hydride
Disilicoethane	Silicon hydride
Disiloxane	Silicyl oxide
Dithionite	Hydrosulfite
Dolomite	Calcium magnesium carbonate
Domeykite	Copper (tri) arsenide
Double nickel salt	Ammonium nickel sulfate
Dysprosia	Dyprosium oxide
Epsom salt	Magnesium sulfate
Erbia	Erbium oxide
Erythrite	Cobalt *ortho*arsenate (ous)

SYNONYM INDEX (Continued)

Compound sought	Listed
Erythrosiderite	Potassium iron chloride
Ethylate	Ethoxide
Ethylxanthate	Xanthate
Ethylxanthogenate	Copper Xanthate
Euclase	Beryllium aluminum silicate
Europia	Europium oxide
Ferric salts	under Iron
Ferrosoferric	under Iron
Ferrous salts	under Iron
Fischer's salt	Potassium nitrocobaltate (III)
Fluellite	Aluminum fluoride
Fluorine oxide	Oxygen fluoride
Fluorite	Calcium fluoride
Fluorophosphate, etc.	Fluophosphate, etc.
Fusible white precipitate	Mercury chloride (ic) diammine
Gadolinia	Gadolinium oxide
Gahnite	Zinc aluminate
Galena	Lead sulfide
Galloethane	Gallium hydride
Germane	Germanium hydride, tetra-
Germanium bromoform	Germane, tribromo-
Germanium chloroform	Germane, trichloro-
Gibbsite	Aluminum oxide
Glauber's salt	Sodium sulfate
Glucinum	Beryllium
Goethite	Iron hydroxide
Gold sodium thiosulfate	Sodium thiosulfateoaurate (I)
Goslarite	Zinc sulfate
Greenockite	Cadmium sulfide
Guanajuatite	Bismuth selenide, tri-
Guanite	Ammonium magnesium phosphate
Gypsum	Calcium sulfate
Hafnia	Hafnium oxide
Halite	Sodium chloride
Hambergite	Beryllium *ortho*borate, basic
Hauerite	Manganese sulfide (ic)
Hausmannite	Manganese oxide (ous, ic)
Heazlewoodite	Nickel sulfide, sub-
Heavy hydrogen	Deuterium
Heavy water	Deuterium oxide
Hematite	Iron oxide (ic)
Hemimorphite	Zinc silicate
Hessite	Silver telluride
Hexaantipyrineyttrium *per*chlorate	under Yttrium complexes
Hexaantipyrineyttrium iodide	under Yttrium complexes
Hexaborane	Boron hydride
Hexabromodisilane	Silicon (di-) bromide, hexa (di-)
Hexabromoethane	Carbon (di-) bromide, hexa
Hexachlorodisilane	Silicon (di-) chloride, hexa-
Hexachloroethane	Carbon (di-) chloride, hexa-
Hexaiododisilane	Silicon (di-) iodide, hexa-
Hexamminechromium (III) chloride	under Chromium complexes
Hexamminecobalt (III) chloride	under Cobalt complexes
Hexamminecobalt (III) *per*rhenate	under Cobalt complexes
Hexaureachromium (III) fluosilicate	under Chromium complexes
Hexaureachromium (III) *per*rhenate	under Chromium complexes
Hieratite	Potassium fluosilicate
Hoernesite	Magnesium *ortho*arsenate
Hopeite, α	Zinc *ortho*phosphate
Hopeite, β-	Zinc *ortho*phosphate
Hyacinth	Zinc *ortho*silicate
Hydrargillite	Aluminum oxide
Hydrazonium salts	under Hydrazine
Hydriodic acid	Hydrogen iodide
Hydrobromic acid	Hydrogen bromide
Hydrocerussite	Lead carbonate, basic
Hydrochloric acid	Hydrogen chloride
Hydrocyanic acid	Hydrogen cyanide
Hydrocyanite	Copper sulfate (ic)
Hydrofluosilicic acid	Fluosilicic acid
Hydromagnesite	Magnesium carbonate, basic
Hydroxide	Oxide (for aluminum, iron, etc.)
Hydroxoplatinic acid	Platinum oxide, di- (ic)
Hydroxylammonium salts	under Hydroxylamine
Hyposulfite	Thiosulfate, hydrosulfite
Infusible white precipitate	Mercury chloride (ic), ammonobasic
Iodide of Millon's base	Mercury iodide (ic), aquobasic ammonobasic
Iodine hydroxide	Iodous acid, hypo-
Iod(o)azide	Iodine azide
Iodyrite	Silver iodide
Kainite	Potassium magnesium chloride sulfate
Kalinite	Potassium aluminum sulfate
Kaluszite	Potassium calcium sulfate
Kieserite	Magnesium sulfate
Köttigite	Zinc *ortho*arsenate
Krausite	Potassium iron sulfate (ic)
Krugite	Potassium calcium magnesium sulfate
Lanarkite	Lead sulfate, basic

SYNONYM INDEX (Continued)

Compound sought	Listed
Langbeinite	Potassium magnesium sulfate
Lansfordite	Magnesium carbonate
Lanthana	Lanthanum oxide
Laurionite	Lead oxychloride
Laurite	Ruthenium sulfide
Lautarite	Calcium iodate
Lawrencite	Iron chloride (ous)
Lechatelierite	Silicon oxide, di-
Leonite	Potassium magnesium sulfate
Lime	Calcium oxide
Litharge	Lead oxide, mono-
Magnesia	Magnesium oxide
Magnesite	Magnesium carbonate
Magnetite	Iron oxide, ferrosoferric
Malachite	Copper carbonate, basic (ic)
Manganite	Manganese hydroxide (ic)
Manganolangbeinite	Potassium manganese sulfate (ic)
Manganosite	Manganese oxide, mon- (ous)
Marcasite	Iron sulfide, di-
Marshite	Copper iodide (ous)
Mascagnite	Ammonium sulfate
Massicot	Lead oxide, mono-
Matlockite	Lead oxychloride
Melanterite	Iron sulfate (ous)
Mendipite	Lead oxychloride
Mercallite	Potassium sulfate, hydrogen
Mercuric bromide, ammonobasic, and similar compounds	under Mercury-nitrogen compounds
Merwinite	Calcium magnesium *ortho*silicate
Metabisulfite	*Pyro*sulfite
Metacinnabarite	Mercury sulfide (ic) (β-)
Methylate	Methoxide
Microcline	Potassium aluminosilicate
Microcosmic salt	Sodium ammonium salt
Millerite	Nickel sulfide, mono-
Minium	Lead oxide, red
Mirabilite	Sodium sulfate
Misenite	Potassium sulfate, hydrogen
Molybdenite	Molybdenum sulfide, di-
Molybdenum blue	Molybdenum oxide
Molybdic anhydride	Molybdenum oxide, tri-
Molybdite	Molybdenum oxide, tri-
Molysite	Iron chloride (ic)
Montanite	Bismuth tellurate
Montroydite	Mercury oxide (ic)
Morenosite	Nickel sulfate
Mosaic gold	Tin sulfide (ic)
Mullite	Aluminum silicate
Muscovite	Potassium aluminosilicate
Nantokite	Copper chloride (ous)
Neodymia	Neodymium oxide
Nesquehonite	Magnesium carbonate
Neutral verdigris	Copper acetate (ic)
Newberyite	Magnesium *ortho*phosphate
Niccolite	Nickel arsenide
Niobic acid	Niobium oxide, pent-
Niton	Radon
Nitratoauric acid	Gold nitrate, hydrogen (ic)
Nitric anhydride	Nitrogen oxide, pent-
Nitrilotrissilane	Silicylamine, tri-
Nitrobarite	Barium nitrate
Nitrogen sulfide	Sulfur nitride
Nitrosoferricyanide	Nitroprusside
Nitrous anhydride	Nitrogen (di-) oxide, tri-
Nitroxyl	Nitryl
Octahedrite	Titanium oxide, di-
Oldhamite	Calcium sulfide
Opal	Silicon oxide, di-
Orpiment	Arsenic sulfide, tri-
Ortho clase	Potassium aluminum silicate
Parahopeite	Zinc *ortho*phosphate
Paralaurionite	Lead oxychloride
Paramelaconite	Copper oxide (ic)
Paris green	Copper acetate *meta*rsenite (ic)
Peligot's salt	Potassium chlorochromate
Pentaborane	Boron hydride
Periclase	Magnesium oxide
Permonosulfuric acid	Sulfuric acid, peroxymono-
Perovskite	Calcium *meta*titanate
Per(di)sulfuric acid	Sulfuric acid, peroxydi
Phenacite	Beryllium *ortho*silicate
Phenate	Phenoxide
Phenolate	Phenoxide
Phosgene	Carbonyl chloride
Phosphine	Hydrogen phosphide
Phosphoric anhydride	Phosphorus oxide pent-
Phosphorus sulfobromide or thiobromide, etc	Thiophosphoryl bromide, etc.
Phosphoryl (tri)amide	Phosphoramide
Phosphoryl bromide, etc.	Phosphorus oxybromide, etc.
Picromerite	Potassium magnesium sulfate
Pinnoite	Magnesium *meta*borate
Plaster of Paris	Calcium sulfate

SYNONYM INDEX (Continued)

Compound sought	Listed
Platinichloride	Chloroplatinate
Platinic hydroxide	Platinum oxide, di- (ic)
Platinochloride	Chloroplatinite
Platinocyanide	Cyanoplatinite
Platinonitrite	Nitroplatinite
Plattnerite	Lead oxide, di-
Plumbic	under Lead
Plumbous	under Lead
Polydymite	Nickel sulfide (ous, ic)
Polyhalite	Potassium calcium magnesium sulfate
Potassamide	Potassium amide
Potassium diboranide	Potassium *di*borane
Potassium fluocolumbate, penta	Potassium fluoniobate, penta-
Potassium oxyfluocolumbate	Potassium oxyfluoniobate
Potassium pentaboranide	Potassium *penta*borane
Praseodymia	Praseodymium oxide, sesqui-
Propylate	Propoxide
Proustite	Silver thioarsenite
Prussiate of soda, yellow	Sodium ferrocyanide
Pseudocotunnite	Potassium lead chloride
Pseudowollastonite	Calcium *meta*silicate (α)
Pyrargyrite	Silver thioantimonite
Pyrite	Iron sulfide (di-)
Pyroborate	*Tetra*borate
Pyrochroite	Manganese hydroxide (ous)
Quartz	Silicon oxide, di-
Racemate	*dl*-Tartrate
Radium emanation	Radon
Raspite	Lead tungstate
Realgar	Arsenic sulfide, di-
Reddingite	Manganese *ortho*phosphate
Rhodanate, rhodanide	Thiocyanate
Rhodochrosite	Manganese carbonate (ous)
Rhodonite	Manganese *meta*silicate (ous)
Rinneite	Potassium iron chloride
Rochelle salt	Potassium sodium tartrate
Roesslerite	Magnesium *ortho*arsenate
Rutile	Titanium oxide, di-
Sal ammoniac	Ammonium chloride
Saltpeter	Potassium nitrate
Samaria	Samarium oxide
Scacchite	Manganese chloride, di-
Scandia	Scandium oxide
Scheele's green	Copper *ortho*arsenite, acid (?) (ic)
Scheelite	Calcium tungstate
Schlippe's salt	Sodium thioantimonate
Schönite	Potassium magnesium sulfate
Scorodite	Iron *ortho*arsenate
Seignette salt	Potassium sodium tartrate
Sellaite	Magnesium fluoride
Senarmontite	Antimony oxide, tri-
Siderite	Iron carbonate (ous)
Siderotil	Iron sulfide
Silanes	Silicon hydrides
Silica	Silicon oxide
Silicobromoform	Silane, tribromo-
Silicochloroform	Silane, trichloro-
Silicofluoride	Fluosilicate
Silicofluoroform	Silane, trifluoro-
Silicoiodoform	Silane, triiodo-
Single nickel salt	Nickel sulfate
Smithsonite	Zinc carbonate
Sodamide	Sodium amide
Soda niter	Sodium nitrate
Sodium heptanoate	Sodium enanthate
Sodium hyposulfite	Sodium thiosulfate, sodium hydrosulfite
Sperrylite	Platinum arsenide
Sphalerite	Zinc sulfide (β)
Spherocobaltite	Cobalt carbonate (ous)
Spinel	Magnesium aluminate
Stannane	Tin hydride
Stercorite	Sodium ammonium phosphate
Stibine	Hydrogen antimonide
Stibnite	Antimony sulfide, tri-
Stolzite	Lead tungstate
Struvite	Ammonium magnesium phosphate
Sulfocarbolate	Phenolsulfonate
Sulfochloride	Chloride sulfide
Sulfocyanate, sulfocyanide	Thiocyanate
Sulfur oxychlorides	Sulfuryl chloride, sulfuryl, pyrochloride, thionyl chloride
Sulfuryl amide	Sulfamide
Sylvite	Potassium chloride
Syngenite	Potassium calcium sulfate
Szmikite	Manganese sulfate (ous)
Tantalic acid	Tantalum oxide, pent-
Tantalum hydroxide	Tantalum oxide, pent-
Tarapacaite	Potassium chromate
Tartar emetic	Potassium antimony tartrate
Tenorite	Copper oxide (ic)
Tephroite	Manganese *ortho*silicate (ous)

SYNONYM INDEX (Continued)

Compound sought	Listed
Terbia	Terbium oxide
Tetrabromoethylene	Carbon (di-) bromo, tetra-
Tetrabromomethane	Carbon bromide, tetra-
Tetrabromosilane	Silicon bromide, tetra-
Tetrachlorodiammineplatinum (IV), *cis*-	under Platinum complexes
Tetrachlorodiammineplatinum (IV), *trans*-	under Platinum complexes
Tetrachloroethylene	Carbon (di-) chloride, tetra-
Tetrachloromethane	Carbon chloride, tetra-
Tetrachlorosilane	Silicon chloride, tetra-
Tetradymite	Bismuth telluride, tri-
Tetrafluoromethane	Carbon fluoride, tetra-
Tetrafluorosilane	Silicon fluoride, tetra
Tetraiodomethane	Carbon iodide, tetra-
Tetraiodosilane	Silicon iodide, tetra-
Tetramminecopper (II) sulfate	under Copper complexes
Tetramminepalladium (II) chloride	under Palladium complexes
Tetrammineplatinum (II) chloride	under Platinum complexes
Tetrammine platinum (II) chloroplatinite	under Platinum complexes
Tetramminezinc *per*rhenate	under Zinc complexes
Tetrapyridinecopper (II) fluosilicate (ic)	under Copper complexes
Tetrapyridinecopper *per*rhenate	under Copper complexes
Tetrapyridinenickel (II) fluosilicate	under Nickel complexes
Tetrapyridinezinc fluosilicate	under Zinc complexes
Tetrasilane	Silicon hydride
Tetrasilicobutane	Silicon hydride
Thenard's blue	Cobalt aluminate
Thenardite	Sodium sulfate
Thermonatrite	Sodium carbonate
Thiophosgene	Thiocarbonyl chloride

Compound sought	Listed
Thoria	Thorium oxide, di-
Thorite	Thorium *ortho*silicate
Thulia	Thulium oxide
Tiemannite	Mercury selenide (ic)
Titanic acids	Titanium oxide, di-
Tridymite	Silicon oxide, di-
Trigermane	Germanium hydride
Trisilane	Silicon hydride
Trisilicopropane	Silicon hydride
Troilite	Iron sulfide (ous)
Uranium nitrate	Uranyl nitrate
Uranyl hydroxide	Uranic acid, meta-
Uranyl oxide	Uranium oxide, tri-
Valentinite	Antimony oxide, tri-
Vanadyl bromide, etc.	Vanadium oxybromide, etc.
Verdigris	Copper acetate
Vermilion	Mercury sulfide (ic) (α)
Villiaumite	Sodium fluoride
Vitriol blue	Copper sulfate (ic)
Vivianite	Iron *ortho*phosphate
Washing soda	Sodium carbonate
Water Glass	Sodium silicate
White arsenic	Arsenic oxide, tri-
White lead	Lead carbonate, basic
White mica	Potassium aluminosilicate
Willemite	Zinc *ortho*silicate
Witherite	Barium carbonate
Wolfram	Tungsten
Wollastonite	Calcium *meta*silicate (β)
Wulfenite	Lead molybdate
Wurtzite	Zinc sulfide (α)
Xanthogenate	Xanthate
Ytterbia	Ytterbium oxide
Yttria	Yttrium oxide
Zaratite	Nickel carbonate, basic
Zincite	Zinc oxide
Zinkosite	Zinc sulfate
Zircon	Zirconium *ortho*silicate
Zirconia	Zirconium oxide, di-
Zirconic acid, meta-	Zirconium oxide, di-
Zirconium hydroxide	Zirconium oxide, di-

PHYSICAL CONSTANTS OF

Metallic salts of organic acids will be

No.	Name	Formula	Mol. wt.	Crystalline form, color and index of refraction
	Aluminum:			
1	Diethylaluminum malonate	$Al(C_7H_{11}O_4)_3$	504.45	wh. need. or pr
2	Triethylaluminum	$Al(C_2H_5)_3$	114.15	col. liq., ign. in air, $1.480^{6.5}$
3	Triethylaluminum etherate	$4Al(C_2H_5)_3 \cdot 3(C_2H_5)_2O$	678.97	col. liq
4	Trimethylaluminum	$Al(CH_3)_3$	72.07	col. liq., ign. in air, 1.432^{12}
5	Triphenylaluminum	$Al(C_6H_5)_3$	258.27	wh. need
	Antimony:			
6	Antimony ethoxide(ous) (triethyl antimonite)	$Sb(C_2H_5O)_3$	256.94	col. liq
7	Pentamethylantimony	$Sb(CH_3)_5$	196.93	existence doubtful
8	Triethylantimony	$Sb(C_2H_5)_3$	208.94	liq
9	Trimethylantimony	$Sb(CH_3)_3$	166.86	liq
10	Triphenylantimony, (triphenylstibine)	$Sb(C_6H_5)_3$	353.06	col. tricl. pl
	Arsenic:			
11	Arsanilic acid (*p*) (*p*-aminophenylarsinic acid)	$H_2NC_6H_4AsO(OH)_2$	217.04	wh. need
12	Arsenoacetic acid	$(AsCH_2COOH)_2$	267.91	sm. yel. need
13	Arsenobenzene	$C_6H_5As{:}AsC_6H_5$	304.02	wh. need
14	Cacodyl oxide (dicacodyl oxide)	$[(CH_3)_2As]_2O$	225.96	col. liq
15	Cacodyl sulfide (dicacodyl sulfide)	$[(CH_3)_2As]_2S$	242.02	oil
16	Dimethylarsine (cacodyl hydride)	$(CH_3)_2AsH$	105.99	col. liq., ign. in air
17	Dimethylarsinic acid (cacodylic acid)	$As(CH_3)_2O \cdot OH$	137.99	odorl., col. pr
18	Dimethylbromarsine (cacodyl bromide)	$(CH_3)_2AsBr$	184.89	yel. oil
19	Dimethylchlorarsine (cacodyl chloride)	$(CH_3)_2AsCl$	140.44	col. liq., infl
20	Methylarsine	CH_3AsH_2	91.96	col. liq
21	Phenylarsonic acid (benzene arsonic acid)	$C_6H_5AsO_3H_2$	202.03	col. pr
22	Tetraethyldiarsine (ethyl cacodyl)	$[(C_2H_5)_2As]_2$	266.06	oil
23	Tetraethyldiarsyl	$[As(C_2H_5)_2]_2$	266.06	liq
24	Tetramethyldiarsyl	$[As(CH_3)_2]_2$	209.96	col.-yel. oily liq., highly poisonous
25	Triethylarsine (arsenic triethyl)	$As(C_2H_5)_3$	162.09	col. liq
26	Trimethylarsine (arsenic trimethyl)	$As(CH_3)_3$	120.01	col. liq
27	Triphenylarsine (arsenic triphenyl)	$As(C_6H_5)_3$	306.21	wh. need. or rhomb. pl., 1.6139^{43}
	Beryllium:			
28	Di-*n*-butylberyllium	$Be(C_4H_9)_2$	123.25	col. liq
29	Diethylberyllium	$Be(C_2H_5)_2$	67.14	col. liq
30	Dimethylberyllium	$Be(CH_3)_2$	39.09	wh. need
31	Dipropylberyllium	$Be(C_3H_7)_2$	95.19	liq
	Bismuth:			
32	Methylbismuthine	$CH_3 \cdot BiH_2$	226.05	liq. (exist. quest.)
33	Triethylbismuthine (bismuth triethyl)	$Bi(C_2H_5)_3$	296.18	liq
34	Trimethylbismuthine (bismuth trimethyl)	$Bi(CH_3)_3$	254.10	liq

METAL-ORGANIC COMPOUNDS

found in the preceding section of the table.

INTERNATIONAL UNION RULES FOR THE NAMING OF ORGANIC COMPOUNDS

Editor's Note.—These rules are taken from the "Definitive Report of the Commission on the Reform of the Nomenclature of Organic Chemistry," which was unanimously adopted by the Commission and by the Council of the International Union of Chemistry at Liége in 1930. A translation of the report, with comments, appeared in the *Journal of the American Chemical Society*, **55**, 3905–25 (1933), and the reader is referred there for the full text and more extended comments. The comments here given in fine type are the editor's. A. M. P.

I. General

1. As few changes as possible will be made in terminology universally adopted.

2. For the present, only the nomenclature of compounds of known constitution will be dealt with; the question of substances of imperfectly known constitution is postponed.

3. The precise form of words, endings, etc., prescribed in the rules should be adapted to the genius of each language by the subcommittees.

II. Hydrocarbons

4. The ending *ane* is adopted for saturated hydrocarbons. Open-chain hydrocarbons will have the generic name *alkanes*.

5. The present names of the first four normal saturated hydrocarbons (methane, ethane, propane, butane) are retained. Names derived from the Greek or Latin numerals will be used for those having more than four atoms of carbon.

As the names in this series are also used in forming names of unsaturated hydrocarbons, of alcohols, aldehydes, acids, etc. a list of them is here given, with the numbers of carbon atoms:

1	Methane
2	Ethane
3	Propane
4	Butane
5	Pentane
6	Hexane
7	Heptane
8	Octane
9	Nonane
10	Decane
11	Hendecane (Undecane)
12	Dodecane
13	Tridecane
14	Tetradecane
15	Pentadecane
16	Hexadecane
17	Heptadecane
18	Octadecane
19	Nonadecane
20	Eicosane
21	Heneicosane
22	Docosane
23	Tricosane
24	Tetracosane
25	Pentacosane
26	Hexacosane
27	Heptacosane
28	Octacosane
29	Nonacosane
30	Triacontane
31	Hentriacontane
32	Dotriacontane
33	Tritriacontane
34	Tetratriacontane
35	Pentatriacontane
36	Hexatriacontane
37	Heptatriacontane
38	Octatriacontane
39	Nonatriacontane
40	Tetracontane
41	Hentetracontane
42	Dotetracontane
43	Tritetracontane
44	Tetratetracontane
45	Pentatetracontane
46	Hexatetracontane
47	Heptatetracontane
48	Octatetracontane
49	Nonatetracontane
50	Pentacontane
51	Henpentacontane
52	Dopentacontane
53	Tripentacontane

54 Tetrapentacontane
55 Pentapentacontane
56 Hexapentacontane
57 Heptapentacontane
58 Octapentacontane
59 Nonapentacontane
60 Hexacontane

6. Branched-chain hydrocarbons are regarded as derivatives of the normal hydrocarbons; their names will be referred to the longest normal chain present in the formula by adding to it the designations of the side chains. In case of ambiguity, or if a simpler name would result, that chain which admits of the maximum of substitutions will be selected as the fundamental chain.

A simple example is 2-methylbutane, $CH_3CH(CH_3)CH_2CH_3$. The principle of "maximum of substitutions" may be illustrated as follows: In the compound

$$\begin{array}{l} CH_3CH_2CH_2CH_2\overset{}{C}HCH_2CH_2CH_2CH_3 \\ \qquad\qquad\qquad\qquad\qquad | \\ \qquad\qquad\qquad\qquad\quad CH(CH_3)CH(CH_3)CH_3 \end{array}$$

the longest straight chain contains nine carbon atoms, which would lead to the name 5-(1, 2-dimethylpropyl)nonane; the number of substitutions in the main chain is only one, but the radical is a complicated one. By selecting a chain of eight we get three substitutions of simpler radicals and arrive at the name 4-butyl-2,3-dimethyloctane. Rules 6 and 7 apply to saturated hydrocarbons only.

7. In case there are several side chains, the order in which such chains are named will correspond to the order of their complexity. The chain having the greatest number of secondary and tertiary atoms will be considered the most complex. The alphabetic order may also be followed in such cases.

Two possible orders to be followed in arranging the names of substituting radicals in a compound are here referred to. In the "order of complexity" the radical of lowest weight comes first, then that of next lowest weight, and so on; of those having the same weight the least branched comes first and the most branched last, thus: methyl, ethyl, propyl, isopropyl, butyl, isobutyl, etc. The "alphabetic order" would of course be: butyl, ethyl, isobutyl, isopropyl, methyl, propyl (or else butyl, *iso*butyl, ethyl, methyl, propyl, *iso*propyl). (The alphabetic order is followed in the Organic Table in this handbook.)

8. In the names of open-chain unsaturated hydrocarbons having one double bond the ending *ane* of the corresponding saturated hydrocarbon will be replaced by the ending *ene;* if there are two double bonds, the ending will be *diene*, etc. These hydrocarbons will bear the generic names *alkenes*, *alkadienes*, *alkatrienes*, etc. Examples: propene, hexene, etc.

9. The names of triple-bond hydrocarbons will end in *yne*, *diyne*, etc. They will bear the generic name *alkynes.* Examples: propyne, heptyne, etc.

The ending *-yne* replaces *-ine* because the latter is reserved for bases (see Rule 33).

10. If there are both double and triple bonds in the fundamental chain the endings *enyne*, *dienyne*, etc., will be used. The generic names of these hydrocarbons will be *alkenynes*, *alkadienynes*, etc.

The double bonds are expressed first in the name (ene before yne) and take precedence in numbering (cf. Rule 64). Example: $CH_2:CHCH:CH\text{-}C:CH$, hexa-1,3-dien-5-yne, not hex-1-yne-3,5-diene. No provision is made for branched unsaturated hydrocarbons. It seems best, for general use, to select as the fundamental straight chain the longest one that contains the maximum of double and triple bonds. Example: $CH_2:C(C_2H_5)CH_2CH_3$, 2-ethyl-1-butene, not 3-methylenepentane.

11. Saturated monocyclic hydrocarbons will take the names of the corresponding open-chain saturated hydrocarbons, preceded by the prefix *cyclo*. They will bear the generic name *cycloalkanes*.

Examples: cyclopropane, cyclobutane, cycloheptane.

12. When they are unsaturated, rules 8–10 will be applied. However, in the case of partially saturated polycyclic aromatic compounds the prefix *hydro*, preceded by *di-*, *tetra-*, etc., will be used. Example: dihydroanthracene.

Further examples: cyclobutadiene, cyclohexene (not tetrahydrobenzene).

13. Aromatic hydrocarbons will be denoted by the ending *ene* and will otherwise retain their customary names. However, the name *phene* may be used instead of benzene.

Examples: benzene, toluene, xylene (not benzol, toluol, xylol).

III. Fundamental Heterocyclic Compounds

14. The endings of customary names, endings which do not correspond to the function of the substance, will undergo the following modifications, so far as they are in accord with the genius of each language: (a) The ending *ol* will be changed to *ole*. Example: pyrrole. (b) The ending *ane* will be changed to *an*. Example: pyran.

15. When nitrogenous heterocycles not having the ending *ine* give basic compounds on progressive hydrogenation, such derivation will be indicated by the successive endings *ine*, *idine*. Examples: pyrrole, pyrroline, pyrrolidine; oxazole, oxazoline.

16. The ending *a* is adopted for hetero atoms occurring in a ring. Oxygen will accordingly be indicated by *oxa*, sulfur by *thia*, nitrogen by *aza*, etc. The letter *a* may be elided before a vowel. Examples: thiadiazole, oxadiazole, thiazine, oxazine.

While the universally accepted names of heterocyclic compounds are retained, the names of other heterocyclic compounds are derived from that of the corresponding homocyclic compound by adding to it the names of the hetero atoms ending in *a*. Example: 2, 7, 9-triazaphenanthrene.

The custom of naming complex heterocyclic ring systems from the names of their component rings (as, anthrapyrrole, naphthopyridine) is so "universally accepted" that it will no doubt continue to be followed. The rule adds a useful new device for certain cases.

IV. Simple Functions

17. Substances of simple functions are defined as those containing a function of one kind only, which may be repeated several times in the same molecule.

That is, an alcohol may have one, two or more OH groups and still be a substance of simple function, while a hydroxy aldehyde or an amino acid is one of complex function.

18. When there is only one functional group, the fundamental chain will be selected so as to contain this group. When there are several functional groups the fundamental chain will be selected so as to contain the maximum number of these groups.

Example: $CH_3CH_2CH(COOH)_2$, 2-ethylpropanedioic acid (ethylmalonic acid). According to the original Geneva system it was butanoic-2-methyloic acid.

19. Halogen derivatives will be designated by the name of the hydrocarbon from which they are derived, preceded by a prefix indicating the nature and number of the halogen atoms.

Examples: C_2H_5Cl, chloroethane; CH_2BrCH_2Br, 1, 2-dibromoethane.

20. Alcohols and phenols will be given the name of the hydrocarbon from which they are derived, followed by the suffix *ol.* In accordance with rule 1 names universally adopted will be retained, as: phenol, cresol, naphthol, etc.

This nomenclature may also be applied to heterocycles. Example: quinolinol.

Further examples: $CH_3CHOHCH_3$, 2-propanol; $C_6H_{11}OH$, cyclohexanol.

21. In naming polyhydric alcohols or phenols, one of the forms *di, tri, tetra,* etc., will be inserted between the name of the parent hydrocarbon and the suffix *ol.*

Examples: CH_2OHCH_2OH, 1, 2-ethanediol; *p*-$C_6H_4(OH)_2$, 1, 4-benzenediol.

22. The name *mercaptan* as a suffix is abandoned; this function will be denoted by the suffix *thiol.*

Examples: CH_3SH, methanethiol; CH_2SHCH_2SH, 1, 2-ethanedithiol.

23. Ethers are considered as hydrocarbons in which one or several hydrogen atoms are replaced by alkoxy groups. However, for symmetrical ethers the present nomenclature may be retained. Examples: $CH_3OC_2H_5$, methoxyethane; CH_3OCH_3, methoxymethane or methyl ether.

24. Oxygen linked, in a chain of carbon atoms, to two of these atoms will be denoted by the prefix *epoxy* in all cases where it would be unprofitable to name the substance as a cyclic compound. Examples: ethylene oxide = epoxyethane; epichlorohydrin = 3-chloro-1,2-epoxypropane; tetramethylene oxide = 1,4-epoxybutane.

25. Sulfides, disulfides, sulfoxides and sulfones will be named like the ethers, *oxy* being replaced by *thio*, *dithio*, *sulfinyl* and

sulfonyl, respectively. Examples: $CH_3SO_2C_2H_5$, methylsulfonylethane; $CH_3SC_3H_7$, methylthiopropane; $CH_3CH_2CH_2$-$SOCH_2CH_2CH_2CH_3$, 1-(propylsulfinyl)butane.

26. Aldehydes are characterized by the suffix *al* added to the name of the hydrocarbon from which they are derived; thioaldehydes, by the suffix *thial.* Acetals will be named as 1,1-dialkoxyalkanes.

Examples: CH_3CHO, ethanal; CHOCHO, ethanedial; CH_3CH_2CHS, propanethial; $CH_2CH(OC_2H_5)_2$, 1,1-diethoxyethane; C_6H_5CHO, benzenecarbonal? (cf. rule 32, paragraph 2).

27. Ketones will receive the ending *one.* Diketones, triketones, thioketones will be designated by the suffixes *dione, trione, thione.*

Examples: CH_3COCH_3, 2-propanone; $CH_3COCOCH_3$, 2, 3-butanedione· $CH_3CSCH_2CH_3$, 2-butanethione; cyclohexanone.

28. The name *ketene* is retained.

Example: $(CH_3)_2C{:}CO$, dimethylketene.

29. For acids the rule of the Geneva nomenclature is retained. However, in cases where the use of that nomenclature would not be convenient the carboxyl group will be considered as a substituting group and the name of the acid will be formed by adding to the name of the hydrocarbon the suffix *carbonique* or *carboxylic,* according to the language.

Examples: CH_3CH_2COOH, propanoic acid; $HOOCCH_2COOH$, propanedioic acid; $HOOCCH_2CH(COOH)CH_2COOH$, 1, 2, 3-propanetricarboxylic acid. In the Geneva system the last-named compound would have been called pentanedioic-3-methyloic acid.

30. Acids in which an atom of sulfur replaces an atom of oxygen will be named according to the Geneva nomenclature. Example: ethanethioic, -thiolic, -thionic, -thionothiolic. If the carboxyl is considered as a substituent the compounds will be named *carbothioic* acids. The suffix *carbothiolic* will be used if it is certain that the oxygen of the OH group is replaced by sulfur; the suffix *carbothionic* if it is the oxygen of the CO group; the suffix *carbodithioic* will be used if both oxygen atoms are replaced.

Examples of the two systems of names: CH_3COSH or CH_3CSOH (either one), ethanethioic acid, methanecarbothioic acid; CH_3COSH, ethanethiolic acid, methanecarbothiolic acid; CH_3CSOH, ethanethionic acid, methanecarbothionic acid; CH_3CSSH, ethanethionothiolic acid, methanecarbodithioic acid.

31. The existing conventions will be retained for salts and esters.

Examples: Sodium butanoate or sodium salt of butanoic acid; diethyl 1,2-ethanedicarboxylate or diethyl ester of 1,2-ethanedicarboxylic acid; sodium acetate; methyl succinate.

32. Acid anhydrides will retain their present mode of designation according to the names of the corresponding acids. For names formed in accordance with the Geneva nomenclature,

the amides, amidoximes, amidines, imides and nitriles will be named like the acids by adding to the name of the corresponding hydrocarbon the endings *amide*, *amidine*, *amidoxime*, *imide*, and *nitrile*, respectively, while the halides will be named by combining *chloride*, etc., with the name of the radical. Examples: C_3H_7COCl, butanoyl chloride; $C_3H_7CONH_2$, butanamide; etc.

If the carboxyl is considered as a substituent the endings *carbonamide*, *carbonamidine*, *carbonamidoxime*, *carbonimide*, *carbonitrile* will be used. Examples: C_3H_7COCl, propanecarbonyl chloride; $C_3H_7CONH_2$, propanecarbonamide; etc.

33. The ending *ine* is reserved exclusively for nitrogenous bases. The present nomenclature of monoamines is retained. For polyamines, the name of the hydrocarbon will be followed by the suffixes *diamine*, *triamine*, etc.

For aliphatic compounds containing quinquevalent nitrogen the ending *ine* will be changed to *onium*. For cyclic substances containing quinquevalent nitrogen in the ring the ending *ine* will be changed to *inium;* for those with the ending *ole*, this will be changed to *olium*. Examples: pyridine, pyridinium; imidazole, imidazolium.

Further examples: CH_3NH_2, methylamine; $(CH_3)_2NH$, dimethylamine; $(CH_3)_3N$, trimethylamine; $NH_2CH_2CH_2NH_2$, 1,2-ethanediamine; dextrin (not dextrine); glycerol (not glycerine).

34. (revised 1938) (a) Derivatives of hydrogen arsenide, AsH_3, will be named like the amines and their derivatives, with the ending *arsine*. The univalent radical $-AsH_2$ will be designated by the prefix *arsino*.

Examples: CH_3AsH_2, methylarsine; $(CH_3)_3As$, trimethylarsine; $(CH_3)_2AsCl$, chlorodimethylarsine; $(CH_3)_3AsO$, trimethylarsine oxide; $H_2AsCH_2CH_2AsH_2$, 1, 2-diarsinoethane or ethane-1, 2-diarsine; $(C_2H_5)_4AsOH$, tetraethylarsonium hydroxide; $(CH_3)_2AsAs(CH_3)_2$, tetramethylbiarsine.

(b) Acids of the types $RHAs(:O)OH$ and $RR'As(:O)OH$ will be named *arsinic* acids; those of the type $RAs(:O)(OH)_2$ will be named *arsonic acids*. The radical $>AsO_2H$ will be designated by the prefix *arsinico*, the radical $-AsO_3H_2$ by the prefix *arsono*.

Examples: $(CH_3)_2AsO_2H$, dimethylarsinic acid; $C_6H_5AsO_3H_2$, benzenearsonic acid.

(c) Rules *a* and *b* are applicable to the analogous compounds of phosphorus and antimony, the syllable "ars" being replaced respectively by *phosph* or *stib*.

(d) The following list includes the prefixes and suffixes applicable to the most common compounds of phosphorus, arsenic and antimony:

Radical	*Prefix*	*Suffix*
$-AsH_2$	arsino	arsine
$-AsO$	arsenoso	
$-AsO_2$	arso	
$>As(:O)OH$	arsinico	arsinic
$-As(:O)(OH)_2$	arsono	arsonic
$-As = As-$	arseno	
$-PH_2$	phosphino	phosphine
$-PO$	phosphoroso	
$-PO_2$	phospho	
$>P(:O)OH$	phosphinico	phosphinic
$-P(:O)(OH)_2$	phosphono	phosphonic
$-P = P-$	phosphoro	
$-P = N-$	phosphazo	
$-P = As-$	phospharseno	
$-SbH_2$	stibino	stibine
$-SbO$	stiboso	
$-SbO_2$	stibo	
$>Sb(:O)OH$	stibinico	stibinic
$-Sb(:O)(OH)_2$	stibono	stibonic
$-Sb = Sb-$	antimono	
$-Sb = As-$	stibarseno	

(e) Derivatives of bismuthine, BiH_3, will be named like the arsines.

(f) Compounds of arsenic, phosphorus, antimony and bismuth which cannot be named clearly by the preceding rules will be named as derivatives of arsines, phosphines, stibines or bismuthines or (if possible) as organometallic derivatives (rule 48).

Examples: CH_3BiO, methylbismuth oxide; CH_3SbCl_4, methylantimony tetrachloride; $(C_6H_5)_2AsOC_2H_5$, ethoxydiphenylarsine; $(CH_3)_2AsOH$, hydroxydimethylarsine or dimethylarsenic hydroxide, CH_3SbS, methylantimony sulfide; $[(CH_3)_2As]_2O$, bis(dimethylarsenic) oxide or cacodyl oxide.

35. Compounds derived from hydroxylamine by replacement of the hydrogen of the hydroxyl will be regarded as alkoxy derivatives; those in which an atom of hydrogen of the NH_2 group is replaced, as alkylhydroxylamines. Oximes will be named by adding the suffix *oxime* to the name of the corresponding aldehyde, ketone or quinone. Examples: $C_2H_5ONH_2$ ethoxyamine; C_2H_5NHOH, ethylhydroxylamine.

Further examples: $CH_3CH_2CH:NOH$, propanal oxime; $CH_3C(:NOH)CH_3$, propanone oxime.

36. The generic term *urea* is retained; it will be used as a suffix for the alkyl and acyl derivatives of urea. Examples: butylurea, $C_4H_9NHCONH_2$; butyrylurea, $C_3H_7CONHCONH_2$. The bivalent radical -NHCONH- will be named *ureylene.*

37. The generic name *guanidine* is retained.

38. The name *carbylamine* is retained.

Example: C_2H_5NC, ethylcarbylamine (or ethyl isocyanide).

RULES FOR NAMING ORGANIC COMPOUNDS (Continued)

39. Isocyanic and isothiocyanic esters (RNCO, RNCS) will be named *isocyanates* and *isothiocyanates*.

40. The name *cyanate* is reserved for true esters which on saponification yield cyanic acid or its hydration products. The name *sulfocyanate* will be replaced by *thiocyanate*.

41. Nitro derivatives: no change in the present nomenclature.

Examples: C_6H_5NO, nitrosobenzene; $(NO_2)_3C_6H_2OH$, trinitrophenol.

42. Azo derivatives: the forms *azo*, *azoxy* are retained.

43. (a) Diazonium compounds, RN_2X, are named by addition of the suffix *diazonium* to the name of the parent substance (benzenediazonium chloride).

(b) Compounds having the same empirical formula but containing trivalent nitrogen will be named by replacing diazonium with *diazo* (benzenediazohydroxide).

(c) Substances of the type RN_2OM will be named *diazoates*.

(d) Compounds in which the two nitrogen atoms are united to a single carbon atom will be designated by the prefix *diazo* (diazomethane, diazoacetic acid).

(e) The term *diazoamino* is retained; however, these compounds may also be regarded as derivatives of triazene.

(f) Derivatives of the substances $H_2NNHNHNH_2$; $NH{:}NNHNH_2$; $NH{:}NNHN{:}NH$ will be named *tetrazanes*, *tetrazenes*, *pentazdienes*, etc.

Examples: (a) $C_6H_5N({:}N)Cl$, benzenediazonium chloride; (b) $C_6H_5N{:}NOH$, benzenediazohydroxide; (c) $C_6H_5N{:}NONa$, sodium benzenediazoate; (d) N_2CH_2, diazomethane; N_2CH_2COOH, diazoacetic acid, diazoethanoic acid or diazomethanecarboxylic acid; (e) $C_6H_5N{:}NNHC_6H_5$, diazoaminobenzene or 1,3-diphenyltriazene, (f) $C_6H_5NHNHNHNHC_6H_5$, 1,4-diphenyltetrazane; $C_6H_5N{:}NNHNH_2$, 1-phenyl-1-tetrazene

44. Hydrazines are designated by the name of the alkyl radicals from which they are derived, followed by the suffix *hydrazine*. In cases where the amino group of carbonamides is replaced by the hydrazino group, the suffix *hydrazide* will be used. Hydrazo derivatives are regarded as derivatives of hydrazine. Examples: CH_3NHNH_2, methylhydrazine; $C_2H_5NHNHC_3H_7$, 1-ethyl-2-propylhydrazine; $C_3H_7CONHNH_2$, butyrohydrazide or propanecarbohydrazide.

45. Hydrazones and semicarbazones are named like the oximes. The term *osazone* is retained.

Examples: $CH_3CH{:}NNHC_6H_5$, ethanal (or acetaldehyde) phenylhydrazone: $(CH_3)_2C{:}NNHCONH_2$, propanone (or acetone) semicarbazone.

46. The name *quinone* is retained.

Examples: *p*-benzoquinone or *p*-quinone, 1,2-naphthoquinone or 1,2-naphthaquinone, phenanthrenequinone or phenanthraquinone

47. Sulfonic and sulfinic acids will be designated by adding the suffixes *sulfonic* and *sulfinic* to the name of the hydrocarbon.

The analogous acids of selenium and tellurium will bear the names *alkaneselenonic* and *-seleninic* acids; *alkanetelluronic* and *-tellurinic* acids.

RULES FOR NAMING ORGANIC COMPOUNDS
(Continued)

Examples: $C_2H_5SO_3H$, ethanesulfonic acid; $C_{10}H_6(SO_2H)_2$, naphthalenedisulfinic acid, CH_3SeO_3H, methaneselenonic acid; $C_6H_5TeO_2H$. benzenetellurinic acid.

48. Organometallic compounds will be designated by the names of the organic radicals united to the metal which they contain, followed by the name of the metal. Examples: dimethylzinc, tetraethyllead, methylmagnesium chloride.

However, if the metal is united in a complex manner it may be considered as a substituent Example: $ClHgC_6H_4CO_2H$, chloromercuribenzoic acid.

49*a* (revised 1938)

I. Cyclic hydrocarbons with aliphatic side chains are to be named according to one of the two following methods: (α) The radical names denoting the side chains are prefixed to the name of the cyclic hydrocarbon. (β) The cyclic hydrocarbon residue, if it can be named as a radical, is considered a substituent of the aliphatic chain. Naming according to (α) is in general preferable when the side chain is short or when several side chains are present. Naming according to (β) is more convenient when the side chain is long, and particularly when the cyclic hydrocarbon residue is not at the end of this chain.

Examples: (α) $C_6H_5C_2H_3$, ethylbenzene; $CH_3C_6H_4C_2H_5$, methylethylbenzene; $C_{10}H_7CH{:}CH_2$, ethenylnaphthalene.
(β) $CH_3CH(C_6H_5)(CH_2)_5CH_3$, 2-phenyloctane; p-$(CH_3)_2CHC_6H_4CH(CH_3)CH(CH_3)(CH_2)_3CH_3$, 3-methyl-2-(4-isopropylphenyl)heptane.

For naming cyclic hydrocarbons with side chains according to (α), it is advisable in many cases to use the common names of simple aromatic hydrocarbons.

Examples: *o*-$CH_3C_6H_4C_2H_5$, 2-ethyltoluene; $(CH_3)_2C_6H_4CH{:}CH_2$(1,3,2), 2-ethenyl-*m*-xylene; $CH_3C_6H_3(C_2H_5)CH(CH_3)_2$(1,2,4), 2-ethyl-*p*-cymene.

II. When several cyclic hydrocarbon residues are united by an aliphatic chain the name of the compound will be derived from that of the aliphatic hydrocarbon, provided radical names are available for the cyclic hydrocarbon residues.

Examples: $C_6H_5CH_2C_6H_5$, diphenylmethane; $C_6H_5CH_2CH(C_6H_5)(CH_2)_2CH_3$, 1,2-diphenylpentane.

If this is not the case, or if the possibility of using a convenient radical name makes it desirable, the name of the compound will be derived from that of one of the cyclic hydrocarbons, on the principle of substitution.

Examples: $C_{11}H_9CH_2C_6H_5$(2), 2-benzylanthracene (better than phenyl-(2-anthryl) methane); $C_{16}H_9CH_2CH_2C_6H_5$, (β-phenylethyl) pyrene.

49*b* (revised 1938). When the cyclic hydrocarbons treated of in rule 49*a* carry functions which can be expressed only by a prefix, the same possibilities for names exist as those indicated in rule 49*a*.

Examples: $C_6H_5CHClCH_2Cl$, 1,2-dichloro-1-phenylethane or (α, β-dichloroethyl) benzene; $C_6H_5CH_2CHCH_3CH_2Cl$, 3-chloro-2-methyl-1-phenylpropane or (γ-chloroisobutyl) benzene; *p*-$ClC_6H_4CH_2CH_2Cl$, 4-chloro-1-(β-chloroethyl) benzene or 2-chloro-1-(4-chlorophenyl) ethane.

For naming derivatives of monocyclic hydrocarbons which have common names, it will be of advantage to employ these names.

RULES FOR NAMING ORGANIC COMPOUNDS
(**Continued**)

Examples: *p*-$ClC_6H_4CH_3$, 4-chlorotoluene (4-chloro-1-methylbenzene); *p*-$ClC_6H_4CH_2Cl$, 4, ω dichlorotoluene (4-chloro-1-(chloromethyl) benzene, 4-chlorobenzyl chloride); $CH_3C_6H_4(NO_2)CH(CH_3)_2$(1,2,4), 2-nitro-*p*-cymene (2-nitro-1-methyl-4-isopropylbenzene)

50. If it is necessary to avoid ambiguity, the names of complex radicals will be placed in parentheses. Examples: (dimethylphenyl)amine = $(CH_3)_2C_6H_3NH_2$; dimethylphenylamine = $C_6H_5N(CH_3)_2$.

V. Complex Functions

51. For compounds of complex function, that is to say, for compounds possessing different functions, only one kind of function (the principal function) will be expressed by the ending of the name. The other functions will be designated by appropriate prefixes.

Example: 2-aminoethanol (not ethanolamine). By rule 1 very commonly used names like phenolsulfonic acid, naphthylaminesulfonic acid might still be used.

52. The following prefixes and suffixes will be used for designating the functions.

Function	Prefix	Suffix
Acid and derivatives	carboxy	carboxylic, carbonyl, carbonamide, etc., or oic, oyl, etc.
Alcohol	hydroxy	ol
Aldehyde	oxo, aldo (for aldehyde O) or formyl (for CHO)	al
Amine	amino	amine
Azo derivative	azo	. . .
Azoxy derivative	azoxy	. . .
Carbonitrile (nitrile)	cyano	carbonitrile or nitrile
Double bond	. . .	ene
Ether	alkoxy	. . .
Ethylene oxide, etc.	epoxy	. . .
Halide	halogeno (halo)	. . .
Hydrazine	hydrazino	hydrazine
Ketone	oxo or keto	one
Mercaptan	mercapto	thiol
Nitro derivative	nitro	. . .
Nitroso derivative	nitroso	. . .
Quinquevalent nitrogen	. . .	onium, inium (olium)
Sulfide	alkylthio	. . .
Sulfinic derivative	sulfino	sulfinic
Sulfone	sulfonyl	. . .
Sulfonic derivative	sulfo	sulfonic
Sulfoxide	sulfinyl	. . .
Triple bond	. . .	yne
Urea	ureido	urea

RULES FOR NAMING ORGANIC COMPOUNDS
(Continued)

The order in which the functions are here listed has no significance; the rules do not establish any general order of precedence (cf. rules 7, 63).

53. The names of derivatives of fundamental heterocyclic substances will be formed according to the preceding rules.

Example: Hydroxyquinolinecarbonamide, not quinolinolcarbonamide.

VI. Radicals

54. Univalent radicals derived from saturated aliphatic hydrocarbons by removal of one atom of hydrogen will be named by replacing the ending *ane* of the hydrocarbon by the ending *yl*.

Examples: methyl, ethyl, pentyl (or amyl), etc. Since isopropylidene is recognized (rule 56) it was no doubt the intention of the Committee to recognize isopropyl similarly.

55. The names of univalent radicals derived from unsaturated aliphatic hydrocarbons will have the endings *enyl*, *ynyl*, *dienyl*, etc., the positions of the double or triple bonds being indicated by numerals or letters where necessary.

Examples: $CH_2{:}CH—$, ethenyl (or vinyl); $CH\vdots C—$, ethynyl; $CH_3—CH{:}CH—CH_2—$, 2-butenyl; $CH_2{:}CH—CH{:}CH—$, 1, 3-butadienyl.

56. Bivalent or trivalent radicals derived from saturated hydrocarbons by removal of 2 or 3 hydrogen atoms from the same carbon atom will be named by replacing the ending *ane* of the hydrocarbon by the endings *ylidene* or *ylidyne*. For radicals derived from unsaturated hydrocarbons, these endings will be added to the name of the hydrocarbon. The names isopropylidene and methylene are retained.

Examples: $CH_2<$, methylene; $CH_3CH<$, ethylidene; $CH_3CH_2CH<$, propylidene; $(CH_3)_2C<$, (1-methylethylidene) or isopropylidene; $CH_3C\vdots$, ethylidyne; $CH_2{:}CH—CH_2CH<$, 3-butenylidene.

57. The names of bivalent radicals derived from aliphatic hydrocarbons by removal of a hydrogen atom from each of the two terminal carbon atoms of the chain will be ethylene, trimethylene, tetramethylene, etc.

Only saturated radicals are provided for: $—CH_2CH_2—$, ethylene; $—CH_2CH_2CH_2—$, trimethylene, etc.

58. Radicals derived from acids by removal of OH will be named by changing the ending carboxylic to *carbonyl* or, if the Geneva nomenclature is used, oic to *oyl*.

Examples: CH_3CO, ethanoyl or methanecarbonyl (or acetyl).

59. Univalent radicals derived from aromatic hydrocarbons by removal of a hydrogen atom from the ring will in principle be named by changing the ending *ene* to *yl*. However, the radicals C_6H_5 and $C_6H_5CH_2$ will continue provisionally to be named phenyl and benzyl respectively. Moreover, certain abbreviations sanctioned by usage are authorized, as *naphthyl* instead of *naphthalyl*.

Examples: $CH_3C_6H_4—$, tolyl (instead of toluyl), anthryl (instead of anthracyl), phenanthryl, fluoryl.

60. Univalent radicals derived from heterocyclic compounds by removal of hydrogen from the ring will be named by changing their endings to *yl*. In cases where this would give rise to ambiguity, merely the final *e* will be changed to *yl*. Examples: pyridine, pyridyl; indole, indolyl; pyrroline, pyrrolinyl; triazole, triazolyl; triazine, triazinyl.

61. Radicals formed by removal of a hydrogen atom from a side chain of a cyclic compound will be regarded as substituted aliphatic radicals.

Examples: $C_6H_5CH_2CH_2$—, (2-phenylethyl); $C_6H_5CH:CHCH_2$—, (3-phenyl-2-propenyl). (For $C_6H_5CH_2$, see rule 59.)

62. In general, special names will not be given to multivalent radicals derived from cyclic compounds by removal of several hydrogen atoms from the ring. In this case prefixes or suffixes will be used. Examples: triaminobenzene or benzenetriamine; dihydroxypyrrole or pyrrolediol.

Comparison with rules 21, 33 and 51 will show that of the names given as examples, "benzenetriamine" and "pyrrolediol" are the ones ordinarily to be preferred (according to the rule of expressing the principal function in the ending of the name where there is a suffix denoting it).

63. The order in which prefixes or radicals are stated (alphabetic order or conventional order) remains optional.

See the comments on rule 7. There is no generally accepted "conventional order" for all prefixes.

VII. Numbering

64. In aliphatic compounds the carbon atoms of the fundamental chain will be numbered from one end to the other with the use of arabic numerals. In case of ambiguity the lowest numbers will be given (1) to the principal function, (2) to double bonds, (3) to triple bonds, (4) to atoms or radicals designated by prefixes. The expression "lowest numbers" signifies those that include the lowest individual number or numbers. Thus, 1, 3, 5 is lower than 2, 4, 6; 1, 5, 5 lower than 2, 6, 6; 1, 2, 5 lower than 1, 4, 5; 1, 1, 3, 4 lower than 1, 2, 2, 4.

Examples: $CH_2:CHCH_2CH_3$, 1-butene (not 3-butene); $CH_2:CHC\vdots CH$, 1-buten-3-yne (not 3-buten-1-yne); $CH_2:CH—CH_2OH$, 2-propen-1-ol (not 1-propen-3-ol; the name allyl alcohol may also be used); $CHCl_2—CH_2CH:CH_2$, 4, 4-dichloro-1-butene. The principle of "low numbers" also applies to cyclic compounds, with due regard to their different structures (e.g., bridges and hetero atoms are usually given preferred positions). Examples: 1, 3-cyclohexadiene; 3-cyclohexen-1-one or simply 3-cyclohexenone; 4, 4-dichlorocyclohexene.

Position of Numbers.—Where shall position numbers be placed, *before* or *after* the parts of the name to which they refer? Usage varies; some chemists place them before, some place them after, some use a combination. The Committee has left full latitude on this point. The examples in the French version usually show the numbers placed after; the examples in these comments follow the practice of *Chemical Abstracts* in being placed before. Each method has certain advantages. In Beilstein numbers placed after are in parentheses, those placed before are not, e.g., "2-methyl-butanol-(4)."

65. Positions in a side chain will be designated by numerals or letters, starting from the point of attachment. The numerals or letters will be in parentheses with the name of the chain.

Examples: $(CH_3)_2CH—$, (1-methylethyl) or isopropyl; $CH_3CHClCH_2—$, (2-chloropropyl). The rule equally permits Greek letters, ordinary letters, primed numbers (1′, 2′), numbers with indices (4^1, 4^2) or other designations.

66. In case of ambiguity in the numbering of atoms or radicals designated by prefixes, the order will be that chosen for the prefixes before the name of the fundamental compound or side chain of which they are substituents.

Example: $CH_2BrCH_2CH_2Cl$, 1-bromo-3-chloropropane (alphabetic order), or 1-chloro-3-bromopropane (order of increasing radical weight). The purpose of the rule is to decide which prefixes shall have which numbers, when the set of numbers (in the above example 1, 3) for the prefixes has been determined.

67. The prefixes, *di*, *tri*, *tetra*, etc. will be used before simple expressions (for example, diethylbutanetriol) and the prefixes *bis*, *tris*, *tetrakis*, etc., before complex expressions. Examples: bis(methylamino)propane, $CH_3NH(CH_2)_3NHCH_3$; bis(dimethylamino)ethane, $(CH_3)_2NCH_2CH_2N(CH_3)_2$. The prefix *bi* will be used only to denote the doubling of a radical or compound; for example, biphenyl.

Additional example of the use of *bi:* *p*-$(C_6H_4CO_2H)_2$, 4, 4′-bibenzoic acid or biphenyl-4, 4′-dicarboxylic acid.

68. A catalog of cyclic systems, with their numberings according both to the existing system and to that of Mr. Patterson, is in preparation under the auspices of the National Research Council of the United States and of the American Chemical Society.

This catalog appeared in 1940 as American Chemical Society Monograph No. 84, "The Ring Index" by Austin M. Patterson and Leonard T. Capell.

In order to avoid all confusion the Commission recommends placing a scheme of numbering at the head of each article.

Steroid ring system

R; nearly always methyl
R′; usually methyl
R″; various groups

A more extensive listing of ring compounds and systems may be found in the following:

- Chemical Abstracts, annual subject index.
- The Ring Index, Patterson and Capell, Reinhold Publishing Company, 1940.
- Lexikon der Kohlenstoffverbindungen, Richter, Leopold Voss, 1910.

The numbering system for the compounds listed above is that used in The Ring Index.

EXPLANATION OF TABLE

The table presents data for over 5000 compounds. They have been selected to include those of general or commercial importance as well as those commonly met with in the laboratory.

Arrangement. The entries are arranged alphabetically by *parent compounds*, substituting atoms and groups like bromo-, chloro-, ethyl-, methyl-, nitro-, etc. being placed after the rest of the name instead of before it; e.g., Acetic acid, dichloro- (and not Dichloroacetic acid). This practice, which is followed in some of the indexes to journals, makes it possible to bring many derivatives of the same parent together. Radicals such as propyl, butyl and amyl, and also compounds such as butyric acid and valeraldehyde, are assumed to be of normal structure unless otherwise stated.

Nomenclature. Compounds are indexed under their common names wherever these are acceptable, but a large number of *synonyms* and *cross references* are included. In particular, many names formed according to the International Union Rules (see preceding pages) are given and are distinguished by the symbol (*). Trade mark names are in quotations.

An **alphabetic order of substituting radicals** is employed in each name; e.g., Ether, ethyl methyl (not Ether, methyl ethyl). For a table of radicals, see preceding pages.

Acids are entered under their "trivial" names where these exist. Systematic names are derived from trivial names where this is feasible; as, Valeric acid, α-bromo-.

Alcohols. Important alcohols having common names, as Amyl alcohol, Isoamyl alcohol, Propyl alcohol, are so entered. For others the International Union names are used; as, 3-Buten-1-ol.

Aldehydes and **amides** are usually entered under names derived from the acid name; as, Propionaldehyde, Propionamide (from propionic acid).

Amines will be found under their usual names; as, Ethylamine, Triethylamine, Ethylenediamine.

Carbylamines are entered as Ethyl isocyanide, Phenyl isocyanide, etc.

Cyanides. See Nitriles, below.

Esters of organic acids will in general be found under the names of the corresponding acids, but those of glycerol and glycol are under the names of the alcohols. Esters of inorganic acids have independent entries; as, Ethyl sulphate, Ethylsulfuric acid.

Ethers. Simple, unsubstituted ethers occur under their own names; as, Ethyl ether, Phenyl ether. Most other monoethers are under *Ether*; as, Ether, isoamyl phenyl.

Halogen derivatives of hydrocarbons, when simple, are entered under their common names (as, Propyl chloride) or, when more complex, under their International Union names (as, 1-Pentane, 2-chloro-).

Hydrazine derivatives are found under *Hydrazine* or, if monoacyl derivatives, under the name of the corresponding acid (as, Benzoic acid, hydrazide). But **hydrazones** are placed under the corresponding carbonyl compound (as, Acetone, phenylhydrazone).

Hydrocarbons of the aliphatic series are entered under their Geneva (International Union) names; other hydrocarbons, under their commonly accepted names.

Isocyanides (Isonitriles) are named as Ethyl isocyanide, Phenyl isocyanide, etc.

Ketones having simple names are so entered (e.g., Acetone, Acetophenone); others are given International Union names if possible (as, 2-Butanone). Those familiar with "ketone" names will find a number of cross references under *Ketone.*

Mercaptans are named, according to the International Union rule, as Ethanethiol (C_2H_5SH), Benzenethiol (C_6H_5SH), etc.

Metallic salts of organic acids will be found in the preceding table, "Physical Constants of Inorganic Compounds."

Metal-organic compounds should be looked for under the name of the metal; as, Lead, tetraethyl-.

Nitriles (cyanides) are given names derived from the corresponding acid; as, Acetonitrile.

EXPLANATION OF TABLE (Continued)

Oximes are entered under the corresponding carbonyl compound; as, Formaldehyde, oxime.

Phenols will be found under their usual names; as, Phenol, Resorcinol.

Salts of bases are entered under the names of the bases; as, Aniline, hydrochloride. For metal salts of organic acids see the preceding table, "Physical Constants of Inorganic Compounds."

Semicarbazones are placed under the corresponding carbonyl compound; as, Acetone, semicarbazone.

Sulfides, sulfones and **sulfoxides** are treated like ethers (see Ethers, above); as, Ethyl sulfide; Sulfone, ethyl phenyl.

Sulfonic acids are named as Ethanesulfonic acid, Naphthalenedisulfonic acid, etc.

Boldface type is used to distinguish the parent compounds and their substituting radicals. When a parent compound is followed by derivatives its name is not repeated but is replaced in each succeeding entry by a dash.

Formulas. Structural formulas have been given in most cases, and the structure has been indicated as fully as is feasible without taking undue space.

Numbers have been assigned to all compounds to facilitate identification of data on the right hand page and for use in connection with the formula, melting point and boiling point indexes which immediately follow the table. Since the original numbering, some items have been deleted and many others added resulting in occasional breaks in the succession and the occurrence of letters in combination with the numbers.

Crystalline form and **color** are stated in easily interpreted abbreviations. Other important characteristics are often added. The **index of refraction,** follows. For crystals of two or three indices they are invariably given in the order ω, ϵ or α, β, γ. The **specific rotation,** $[\alpha]$, is given for certain compounds. Temperature and wavelength are indicated by the superior and inferior figures and letters following the numerical value. When not otherwise indicated the index of refraction and specific rotation are understood to be at 20°C. and for sodium light.

For example: 1.5236^{20}_{D} indicates an index of refraction of 1.5236 for sodium light ($\lambda = 589.3$ mμ) at 20°C; $[\alpha] - 65.6^{\circ 20}_{D}$ indicates a negative specific rotation of 65.6° for sodium light and a temperature of 20°C.

Density, is normally given in grams per milliliter, at 20°C, numerically equivalent to the specific gravity at 20° referred to water at 4°C. Specific gravity at other temperatures is shown with superior and inferior figures indicating, respectively, the temperature of the substance and that of water to which it is referred. The density of gases is given in grams per liter at 0°C and 760 mm Hg pressure unless otherwise indicated.

Example: 1.536 indicates a density in grams per milliliter at 20°C; 1.634^{25}_{4} indicates a specific gravity of 1.634 at 25°C referred to water at 4°. 2.143g/l indicates the density of a gas at standard conditions, 0°C and 760 mm pressure, as 2.143 grams per liter.

Melting point and **boiling point** are given in °C. Other effects of temperature elevation such as dehydration, sublimation, decomposition explosion are recorded in connection with the melting or boiling points. Decomposition on heating is indicated by the abbreviation d. If decomposition occurs at a definite temperature, the form d. 120 is used, while 120 d. indicates melting or boiling at 120°C with decomposition. Loss of water of crystallization is indicated by — H_2O. The boiling point is stated at normal atmospheric pressure (760 mm of Hg) unless otherwise indicated by a superior figure which shows the pressure in millimeters under which the compound boils at the temperature given.

Example: 125^{720} indicates a boiling point of 125°C at a pressure of 720 mm.

Solubility is stated in grams of substance dissolving in 100 ml of the solvent. Normal room temperatures, 20°C, is assumed unless the temperature is indicated by a superior figure. The term insoluble (i.) must usually be interpreted to mean that a negligible quantity of the compound dissolves. Many compounds commonly regarded as insoluble really dissolve to a slight extent. The terms very soluble (v.s.), soluble (s.), slightly soluble

EXPLANATION OF TABLE (Continued)

(sl.s.) are used for lack of definite figures. Conflicting statements are very common in the literature. Quantitative statements of solubility are likewise subject to uncertainty due to inexact statement of conditions. Values may be variously stated as parts by weight of solute in parts by weight or volume of the solvent or of the solution, and values are often given and quoted in the literature without proper designation. In the large number of values given there are many which are uncertain in this respect.

The form s. d. indicates solubility with more or less decomposition. The occurrence of d. alone in the statement of solubility indicates that decomposition is the primary action. The statement of solubility in acids or alkalis is usually understood to be accompanied by decomposition.

The policy has been followed of giving the solubility in water, ethyl alcohol and ethyl ether first, followed by statements in regard to other solvents.

As examples:

23.4^{20} indicates a solubility of 23.4 grams of the substance in 100 ml of solvent at 20°C.

250 cm^3 al. indicates the solubility of a gas in ethyl alcohol as 250 cm^3 or ml of the gas in 100 ml of alcohol.

∞^{35} indicates that the substance is miscible with the solvent above 35°C.

Molecular weights have been computed to the nearest hundredth according to the atomic weights of 1939.

ABBREVIATIONS

$[\alpha]$	specific rotation
a	acid
abs	absolute
abt	about
ac. a	acetic acid
acet	acetone
al	alcohol
alk	alkali
amor	amorphous
